FUEL JETTISON

Applicable to: ALL

L2 The flight crew can display this procedure by pressing the ECP ABN PROC pb, then selecting the FUEL menu.
When the flight crew activates the procedure, the FUEL SD page automatically appears.

Fuel jettison enables a rapid reduction of aircraft gross weight in order to:
- Comply with the approach and landing climb requirements, or
- Obtain the maximum landing weight (if time permits), or
- Obtain the planned flight profile in the case of engine failure enroute.

It is possible to jettison in any aircraft configuration, and at any speed. However, the height should be sufficient to avoid contamination on the ground (5 000 ft AGL is considered as adequate). The flight crew should coordinate with ATC, and adapt the jettison altitude also depending on local regulations, and/or the emergency of the situation.
Do not jettison in a thunderstorm.
During jettison, avoid flying into the jettisoned fuel (which descends at above 500 ft/min).
The average weight reduction in aircraft weight, due to jettison only, is approximately 5 500 lb/min (330 700 lb/h).

Continued on the following page

  Load alleviation transfers from the outer tanks are inhibited.
  The FQMS will start a gravity transfer from the outer tanks to the feed tanks, as soon as the lowest feed tank quantity goes below 28 700 lb. Simultaneously, the FUEL NORM XFR FAULT alert will trigger, to request the use of the outer tank emergency transfer valves.

FUEL L(R) WING FEED PMPS FAULT

Applicable to: ALL

ANNUNCIATIONS

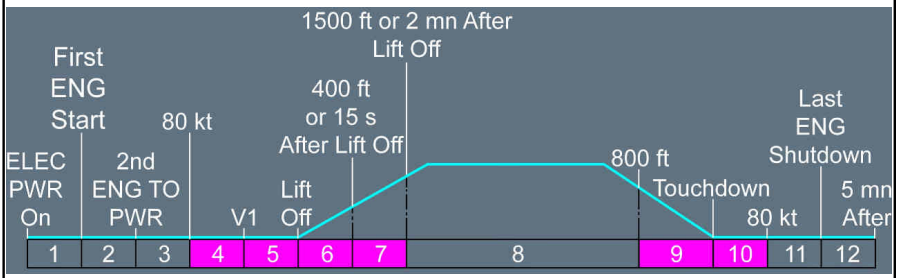
Triggering Conditions:

L2 All left(right) wing feed tank pumps are either:
- Operating either at low pressure, or
- Abnormally not running, or
- Turned off by the flight crew (except in flight phase 1 and 12, or, if required by another ECAM procedure (e.g. FUEL WINGS NOT BALANCED)).

Indications:

Audio	Master Light	Local light	SD page
		 FEED TK 1+2(3+4) MAIN and STBY PMP pb-sw	 FUEL SD Page

Flight Phase Inhibition:



Continued on the following page

FUEL L(R) WING FEED PMPS FAULT (Cont'd)

L2 If both pumps in a feed tank are failed, the fuel in that feed tank can only be fed by gravity.

However, fuel gravity feeding is only possible when the aircraft is below FL 280 (FL 50 / MEA if the flight time above FL 300 is less than 30 min), therefore, as required by ECAM, the flight crew must perform the following actions, in order to maintain cruise altitude as long as possible:

1. Open the crossfeed valves, to feed the left(right) wing engines. During this time, the left(right) wing feed tanks remains full. The other feed tanks receive fuel from the inner, mid and trim tanks, via normal transfers.
   Lateral balance is maintained.
2. Descend to the gravity feed ceiling, when the inner and mid tanks are empty. Close the crossfeed valves. The left(right) wing engines are fed by gravity.
   All feed tanks are emptied simultaneously.

For associated MEL dispatch conditions, *Refer to MEL/ME-ECAM-28 FUEL L(R) WING FEED PMPs FAULT* .

Continued on the following page

FUEL L(R) WING FEED PMPS FAULT (Cont'd)

■ **Before takeoff:**

FEED TK 1(3) MAIN PMP.....OFF
FEED TK 1(3) STBY PMP.....OFF
FEED TK 2(4) MAIN PMP.....OFF
FEED TK 2(4) STBY PMP.....OFF

FEED TK 1(4) : 2900 LBS MAX NOT USABLE

L2 *Both feed tank pumps in feed tank 1(4) are failed, therefore, the fuel in feed tank 1(4) is available for gravity feeding only. However, up to 2 900 lb of fuel may remain trapped in feed tank 1(4).*

L1 FEED TK 2(3) : 4400 LBS MAX NOT USABLE

L2 *Both feed tank pumps in feed tank 2(3) are failed, therefore, the fuel in feed tank 2(3) is available for gravity feeding only. However, up to 4 400 lb of fuel may remain trapped in feed tank 2(3).*

L1 ■ **After takeoff:**

L2 A fuel pipe break on the engine feed line may cause a fuel leak rate that may lead to LOW PRESS conditions of the main and standby pumps associated with the affected engine feed line. The ECAM triggers the FUEL FEED TK 1(2)(3)(4) MAIN+STBY PMPs FAULT alert. If the alert is triggered following a pipe break, the opening of the crossfeed valves may also depressurize the main and standby pumps of the adjacent feed tank because they are now connected to the broken pipe. As a result, the ECAM will trigger the FUEL L(R) WING FEED PMPs FAULT alert. If there is a pipe break on an engine feed line, closing all the crossfeed valves pressurizes again the main and standby pumps in the adjacent feed tank. The FUEL L(R) WING FEED PMPs FAULT alert no longer appears, and is replaced again by the FUEL FEED TK 1(2)(3)(4) MAIN+STBY PMPs FAULT alert.

L1 ALL CROSSFEEDS.....OFF

● **IF NO FUEL LEAK:**

L2 If the FUEL L(R) WING FEED PMPs FAULT alert remains displayed on the ECAM following the closure of all the crossfeed valves, the flight crew should apply the following procedure.
If the flight crew did not previously identify a fuel leak, they should open all the crossfeed valves in order to feed the engines on the affected wing with fuel from the other wing.

● **IF OUTR TK s LEAK SUSPECTED :**

L2 Based on the normal transfer sequence, If the leak is detected late in the flight, according to the normal transfer sequence, the fuel quantity in each feed tank may be as low as 8 800 lb .
Therefore, to minimize the loss of fuel, and ensure a safe diversion, the flight crew must transfer the fuel from the outer tanks earlier than the normal transfer sequence.

L1 OUTR TK s PARTLY NOT USABLE
OUTR TK XFR..... MAN

● **IF INR / MID TK s LEAK SUSPECTED :**

L2 Based on the normal fuel transfer sequence, when there is fuel in the inner and/or mid tanks, the feed tanks and outer tanks are full, and some fuel remains in the trim tank.

Therefore:
- A manual inner or mid tank transfer is not possible because the feed tanks are full
- There is sufficient fuel in the remaining tanks to perform a diversion.

FUEL MAN BALANCING PROCEDURE

Applicable to: ALL

L2 The flight crew may detect:

- A wings imbalance, before the ECAM triggers the FUEL WINGS MAN BALANCING PROCEDURE alert or the FUEL WINGS NOT BALANCED alert, or
- An imbalance between feed tanks 1/2 and 3/4.

This procedure enables the flight crew to manually correct the imbalance.
The flight crew can access and display this procedure by pressing the ABN PROC pb on the ECP, then by selecting the FUEL menu.

Continued on the following page

FUEL MAN BALANCING PROCEDURE (Cont'd)

■ **On ground:**

DELAY T.O

■ **In flight:**

● **IF FEED TKs NOT BALANCED :**

L2 The flight crew should first consider fuel imbalance between two symmetric tanks (i.e. feed tanks 1 and 4, or 2 and 3), as this imbalance creates a lateral moment, and then leads to the extension of flight control surfaces.

L3 *Note: Due to the different sizes of the feed tanks, there is a normal imbalance around 3 300 lb between feed tanks 1/4 and 2/3.*

L1 ● **IF NO FUEL LEAK :**

● **IF FEED TKs 1 & 4 NOT BALANCED:**

FUEL CONSUMPTION INCREASED : FMS PREDICTION DISREGARD

L2 *The flight control laws extend control surfaces in order to counter the lateral moment due to the wings imbalance. The extension of the flight control surfaces increases the fuel consumption.*
Considering the trapped tank as full and the other tanks as empty, the maximum increase of the fuel consumption is 35 % for the feed tanks 1 and 4.

To optimize the fuel consumption:
- *Set the Cost Index (CI) to zero, and use managed speed*
- *Fly the aircraft preferably at FMS optimum FL, or between FMS optimum FL and FMS optimum FL -4 000 ft.*

L2 *The flight crew must stop the manual transfer from the inner(mid) tanks to the feed tanks in order to minimize the risk of overflow of the feed tank.*

L1 TRIM TK XFR.....FWD

ASSOCIATED PROCEDURES

FUEL MAN XFR PROCEDURE
Refer to procedure

● **In flight:**

L2 If the FUEL TRIM TK XFR FAULT alert triggers because of a failure that is different from the inconsistent UP and DOWN information from the landing gear lever:

- The ECAM displays the procedure to perform a manual trim tank transfer (via the pumps or by gravity), or to isolate the trim tank, as described here above
- The ECAM will also display the procedure below. As the flight crew has isolated the trim tank or has initiated a manual pumped or gravity transfer just before, they will not confirm the condition “IF TRIM TK NOT ISOLATED & NO TRIM TK XFR IN PROGRESS” and as a consequence they will not perform the associated action line.

Continued on the following page

FUEL TRIM TK XFR FAULT (Cont'd)

If the FUEL TRIM TK XFR FAULT alert triggers because of the inconsistent UP and DOWN information from the landing gear lever, there is no other associated procedure than the one below. In this case, the flight crew confirms the "IF TRIM TK NOT ISOLATED & NO TRIM TK XFR IN PROGRESS" condition and performs the manual trim tank transfer as soon as the inner tanks are empty.

L1 ● **IF TRIM TK NOT ISOLATED & NO TRIM TK XFR IN PROGRESS :**
WHEN INR TKS EMPTY: TRIM TK XFR..... FWD

L2 *The flight crew should wait for the inner tanks to be empty before they perform the manual trim tank transfer. If they perform the manual trim tank transfer earlier, the FUEL CG AT FWD LIMIT alert may trigger.*

L1 ● **When the trim tank is empty:**

L2 When the trim tank is empty, and after a confirmation time of 5 min , the FQMS logic detects that there is fuel in the inner tanks and starts the automatic transfer from the inner to the feed tanks.

L2 In the case of a green (yellow) hydraulic system failure:

- The flight controls are actuated by the remaining hydraulic system, or by the Electrico-Hydrostatic Actuators (EHA) and the Electrical Backup Hydraulic Actuators (EBHA)
- The flaps operate at half-speed. The slats operate at half-speed if the green hydraulic system is failed
- If the failure of the green (yellow) hydraulic system occurs before landing gear retraction:
  - The Body Landing Gear retracts, if the green hydraulic system is failed
  - The Nose Landing Gear retracts, if the yellow hydraulic system is failed.
    For more information : *Refer to DSC-32-40-20 Landing gear retraction with one hydraulic system failed*
- Landing gear extension is performed by gravity.

Continued on the following page

HYD G (Y) SYS PRESS LO (Cont'd)

● **During taxi-in, one minute after the FLAPS lever is set to 0:**

FOR TAXI : FLAPS SELECT CONF 1+F

L2 *On ground, when the flaps are retracted and if at least one engine is running, the spoilers extend 5° up. This prevents friction between the spoilers and the flaps, which could damage the spoilers.*
When some spoilers are failed, the flaps should remain extended as long as the aircraft is taxiing in order to prevent this friction.

L1 FLAPS SLOW

L2 *Due to the failure of the green (yellow) hydraulic system, only the remaining hydraulic system is available to move the flaps. As a result, the flaps operate at half-speed.*

L1 ● **If G SYS PRESS LO:**

SLATS SLOW

L2 *Due to the failure of the green hydraulic system, only the electric motor is available to move the slats. As a result, the slats operate at half-speed.*

L1 L/G GRVTY EXTN ONLY
LDG DIST AFFECTED

L2 *Landing distance is increased due to the loss of 3 pairs of ground spoilers.*

L1 ● **If G SYS PRESS LO:**

FOR TAXI : STEER ENDURANCE LIMITED

L2 *Normal nose wheel steering (NWS) is lost. ALTN NWS is available.*
The ALTN NWS is designed to be used until the runway is cleared (i.e. to land and to exit the runway). Therefore, the flight crew should anticipate the use of a tug to tow the aircraft to the gate.
The flight crew should avoid a prolonged use of the ALTN NWS because it would result in an ALTN NWS overheat and a disconnection of the NWS.

In alternate nose wheel steering:
- *The maximum steering rate is limited to 10 °/s (instead of 15 °/s for normal NWS)*
- *Damping of the CAPT and the F/O tillers is increased to prevent the flight crew from commanding excessive steering rates.*

  MAX SPEED : 220 KT

L123

DEFERRED PROC

FOR APPROACH:

USE SELECTED SPEED

In some abnormal slats/flaps configurations (e.g. SLATS SYS failure), the FMS does not receive the FLAPS lever position. Thus, the managed speed is not in accordance with the FLAPS lever position. Therefore, as a general rule, when the slats/flaps are in abnormal configuration (e.g. following a dual hydraulic failure, or when slats/flaps are locked), the flight crew must use the selected speed to configure the aircraft for approach and landing.

To prepare the aircraft for landing the flight crew must decelerate the aircraft to the approach speed, as follows:

- *Decelerate the aircraft toward the VFE NEXT- 5 kt . In the case of turbulence, to avoid VFE exceedance, the flight crew may decide to decelerate to a lower speed but above the VLS .*

Continued on the following page

HYD G+Y SYS PRESS LO (Cont'd)

- *When the aircraft reaches the selected speed, the FLAPS lever can be set one step down.*

The above steps are repeated until the FLAPS lever is set to 3.
When the landing configuration is established, aircraft can be decelerated to the computed approach speed.

Note: *The VFE NEXT displayed on the PFD takes into account the abnormal slats/flaps configuration.*

● **If flaps position is less than 3:**
[MFD SURV] TAWS FLAP MODE.....OFF

FOR VFE : USE PFD

The PFD speed scale displays the VFE that is associated with the current abnormal configuration.

VFE ABN CONF (kt)			
	S=0	*0<S≤1*	*S>1*
F=0	*No limitation*	*263*	*220*
0<F≤1	*245*	*243*	*218*
1<F≤2	*243*	*241*	*216*
2<F≤3	*219*	*216*	*196*
F>3	*186*	*184*	*182*

If the slats or flaps are jammed, the VFE s of CONF 1+F and CONF 2 displayed on the PFD and on the ECAM are increased vs. the placard speeds. This is operationally necessary to get a minimum margin between VLS and VFE NEXT, when the slats/flaps are jammed in an intermediate position and flaps lever is in position 0 or 1.
Example: When the slats are jammed at 0.5 ° (0<S≤1) and flap lever is in position 1, the VFE NEXT displayed on the PFD is 243 kt instead of 222 kt , because the VLS may reach 225 kt depending on the A/C weight and altitude when the failure occurs.

FOR LDG : FLAP LVR 3

Note: *The reduced drag causes the aircraft to decelerate more slowly. Therefore, it is recommended that the aircraft is at the landing configuration and approach speed before starting the final approach.*

NO AUTOLAND

As ILS CAT 2 is not available, the flight crew must not perform an automatic landing.

FOR GA : MAINTAIN CURRENT S/F CONF

Applicable to: ALL

ANNUNCIATIONS

Triggering Conditions:

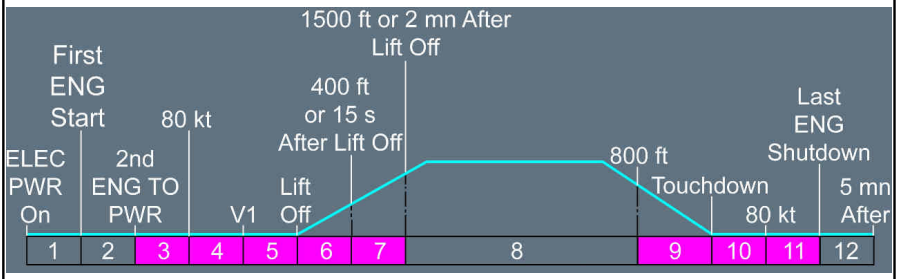
L2 The CAPT PFD/ND, and F/O PFD/ND, are displaying IR data from a unique source.

Indications:

Flight Phase Inhibition:



For associated dispatch condition, *Refer to MEL/ME-ECAM-31-1-22 CDS EFIS IR SINGLE SOURCE*

Crew Awareness.

CDS FWS 1+2 & CPIOM FAULT

Applicable to: ALL

ANNUNCIATIONS

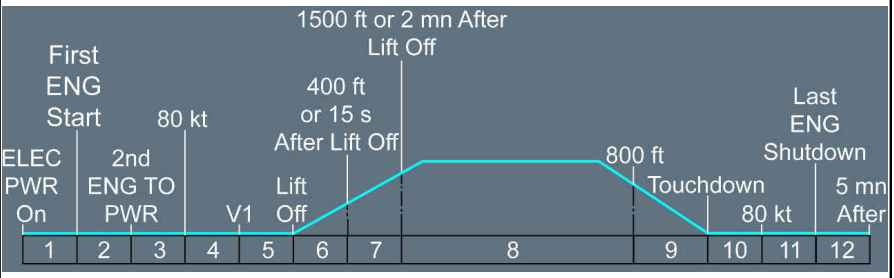
Triggering Conditions:

L2 Both CPIOM groups C, that controls FWS 1+2, are failed.
One or more of the following CPIOM group(s) is (are) failed:

- CPIOM A
- CPIOM B
- CPIOM D
- CPIOM E
- CPIOM F
- CPIOM G

For more details on CPIOM groups, *Refer to DSC-42-10 CPIOMs*
Indications:

Flight Phase Inhibition:



Continued on the following page

CDS FWS 1+2 & CPIOM FAULT (Cont'd)

L2 *Note: If the ECAM caution FWS 1+2 & CPIOM FAULT is triggered while neither FWS 1 FAULT nor FWS 2 FAULT was previously triggered, the caution may be due to a spurious failure of the CDS display. In this case, the ECAM may be still available (aural alerts, master caution, master warn, memos and limitations on PFD, and automatic display of SD pages in case of failure are still available), but can no more display any further alert and procedure on the WD . If occurs, this case is may be due to the display unit itself. Therefore, full ECAM would be recovered, if either the EWD DU is reset (OFF 5 S THEN ON), or the EWD is reconfigured on the SD DU .*

For associated MEL dispatch conditions, *Refer to MEL/ME-ECAM-31-1-22 CDS FWS 1+2 & CPIOM FAULT* .
When both CPIOM groups C are failed :

- ECAM alerts, aural warnings, and MASTER lights will no longer be triggered
- The F/CTL SD page is no longer available
- The WBBC and FCU backup functions are failed.
- CAT 2 approach capability is lost.

During descent and approach preparation, the flight crew must check regularly the general status of the systems on:

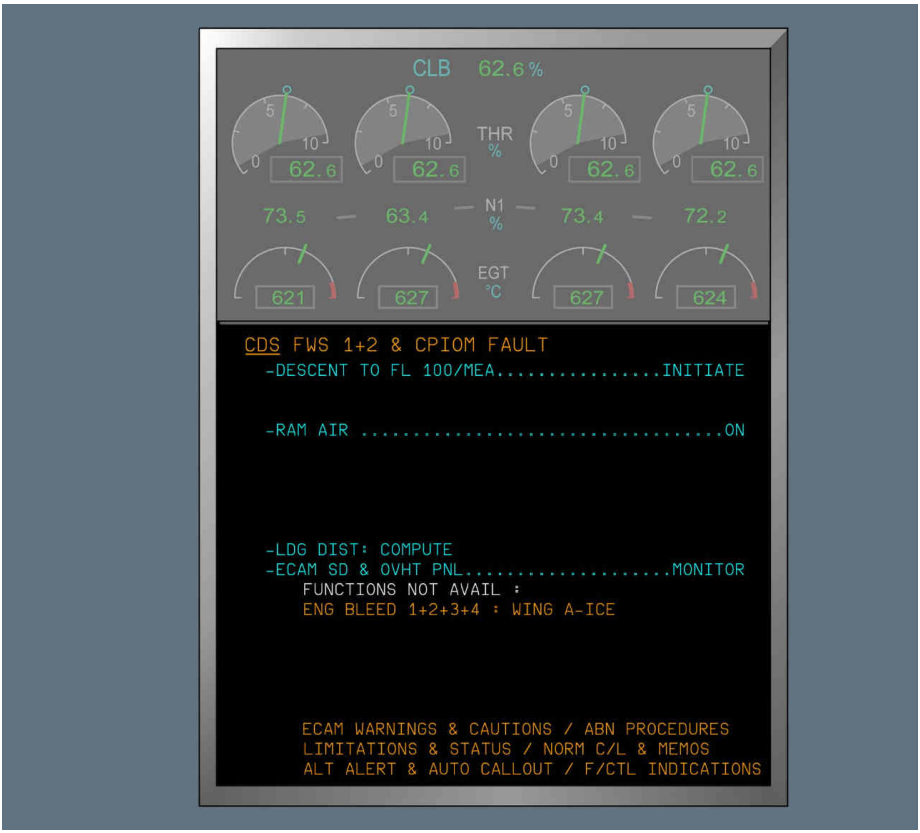
- The overhead panels
- The available SD pages

FWS 1+2 are failed. Therefore, the FWS will no longer manage the space between the action lines, and it will vary according to the affected groups of CPIOM s.

Continued on the following page

CDS FWS 1+2 & CPIOM FAULT (Cont'd)

CPIOM Group C and A Failures



Continued on the following page

CDS FWS 1+2 & CPIOM FAULT (Cont'd)

- **If CPIOM group F is failed:**

LAND ANSA

- **If CPIOM group A is failed:**

DESCENT TO FL 100/MEA.....INITIATE

L2 *The following aircraft system and function are failed:*
- *Bleed air system*
- *Bleed overheat detection.*

The bleed air do not supply the wing anti-ice. Therefore, avoid icing conditions.

L1 - **If CPIOM group B is failed:**

CAB PRESS MAN MODES: DO NOT USE

L2 *The following aircraft functions are failed:*
- *Automatic cabin pressure control*
- *Cabin, and avionics ventilation control*
- *Air generation and temperature control.*

When the CPIOM B is failed, the cabin pressurization system is in backup mode. The cabin altitude target is no longer displayed on the SD: Therefore, the flight crew must not use the cabin pressurization manual system.

L1 IN DES, ABV 7000FT: CAB ALT REGULATED TO 7000FT

L2 *The landing field elevation is fixed at 7 000 ft. Therefore, below 7 000 ft, the outflow valves are open. The cabin altitude is the same as the aircraft altitude, and high descent rate must be avoided.*

L1 BLW 7000FT: CAB ALT = A/C ALT: AVOID HI DES RATE

- **If CPIOM group A is failed:**

RAM AIR.....ON

L2 *Emergency RAM AIR inlets will open to ventilate the cockpit and cabin when the differential pressure goes below 1 PSI .*

L1 - **If CPIOM group F is failed:**

ALL CROSSFEEDS.....OPEN

L2 *The crossfeed valves are open.*

L1 OUTR TK XFR.....MAN / EMER OUTR TK XFR.....MAN

Continued on the following page

CDS FWS 1+2 & CPIOM FAULT (Cont'd)

L2 *FQMS 1+2 are failed. Therefore, manually transfers fuel from the outer tanks to the feed tanks.*
The fuel SD page is failed, therefore the flight crew cannot monitor fuel transfer.
CDS computes the FOB.

L1 INR TKS + MID TKS + TRIM TK: NOT USABLE

● **If CPIOM D group is failed:**

ATC COM VOICE ONLY

L2 *All ATC datalink functions are failed (i.e. ADS, CPDLC, Digital ATIS).*

L1 ● **If CPIOM group G is failed:**

L/G GRVTY EXTN ONLY (MAX SPEED: 220 KT)

L2 *The following aircraft system and functions are failed:*
- *Normal and Alternate braking, Anti-skid*
- *Steering*
- *Normal Landing gear extension/extraction*
- *Tire Pressure Indicating System/Oleo Pressure Monitoring System/Brake Temperature Monitoring System.*

Therefore, landing gear extension is available by gravity only. Use the L/G GRVTY selector to extend by the landing gear by gravity. The maximum speed to extend the landing gear by gravity is 220 kt.

L1 LDG DIST: COMPUTE
ECAM SD & OVHD PNL.....MONITOR

L2 *ECAM SD pages are no longer available for systems hosted by the failed CPIOM groups, or information displayed on the ECAM SD might be affected for other systems.*
Regularly check the cockpit panels for local warnings, and the ECAM SD pages for system checks.
The flight crew should consider using the FCOM on the OIS to display any necessary procedure(s).
Notify the cabin crew that only warnings on the FAP are available.

L1 FUNCTIONS NOT AVAIL :

L2 *The inoperative functions are:*

L1 ● **If CPIOM group A is failed:**

ENG BLEED 1+2+3+4 / WING A-ICE

L2 *Wing anti-ice is not available. Therefore, avoid icing conditions.*

L1 ● **IF CPIOM group F is failed:**

FQMS 1+2 / Jettison

Continued on the following page

CDS FWS 1+2 & CPIOM FAULT (Cont'd)

● **If CPIOM group G is failed:**

LG CTL 1+2 / A-SKID / N/W + B/W STEER

L2 *The emergency braking mode is active, and the landing distance is increased. Refer to performance module.*
For landing, use the rudder and/or the differential braking to steer the aircraft on the runway, because the nose landing gear is free to caster.
After landing, the aircraft must be towed off the runway.

L1 ● **If CPIOM B group is failed:**

FWD + AFT VENT CTL / TEMP CTL

L2 *Temperature regulation in the cabin is degraded. The temperature in some zones may be abnormally low.*

L1 ECAM WARNINGS & CAUTIONS / ABN PROCEDURES

Even if the flight crew applies maximum deflection on the brake pedals, the braking pressure is automatically limited to reduce the risk of tire burst.
In the case of wet runway or more than wet, tire may burst.

DELAY BRAKING UNTIL NLG TOUCHDOWN

The braking pressure limitation is based on the assumption that the landing gears carry the total aircraft weight. Before the NLG touches down, the wings generate significant lift. So the

Temp. target	*SAT*									
300 °C	*-54 °C*	*0*	*16*	*29*	*42*	*53*	*63*	*72*	*81*	*89*
	15 °C	*0*	*19*	*35*	*50*	*63*	*74*	*85*	*94*	*103*
	55 °C	*0*	*22*	*40*	*56*	*70*	*83*	*94*	*104*	*114*

Estimated Brake Cooling Time Table

The flight crew uses the brake cooling time table to estimate a minimum brake cooling time based on the current brake temperature.
The flight crew uses the table when the aircraft is stopped. When the aircraft is stopped for at least 15 min, the flight crew notes the hottest brake temperature displayed on the WHEEL SD page. The flight crew enters the table with this value by the top of the table. Function of the outside temperature displayed on the permanent data of the SD page (SAT), the flight crew reads the time value at the intersection of the line and the column.

Note: Example:
- *SAT= 15 °C*
- *Current maximum brake temperature red on the WHEEL SD page=550 °C*

The flight crew estimated the brake cooling time for a target brake temperature of 300 °C

They read the value at the intersection of:
- *The 550 °C current temperature column*
- *The line associated with the 15 °C SAT.*

74 min is the estimated time corresponding to the brake cooling time for the condition of the day.

For intermediate values, the flight crew interpolates linearly.
The brake cooling time does not take into account the effect of the wind.

Continued on the following page

BRAKES BRAKES HOT (Cont'd)

To increase the precision of the estimated brake cooling time, the flight crew can use the table several times during the brake cooling, taking the hottest brake temperature as a reference.

L/G CTL 1+2 FAULT (Cont'd)

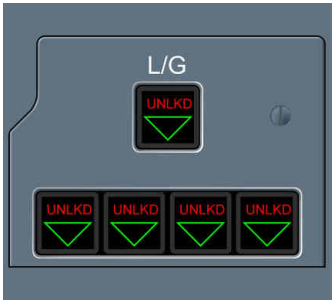
● WHEN L/G LOCKED DOWN OR AFTER 120S



After a landing gear gravity extension the landing gear is downlocked when the associated green triangle is illuminated.
With the landing gear downlocked, the UNLKD red indication will remain illuminated together with the green triangle until the landing gear control lever position is set to down position.

L/G LEVER..... DOWN

Note: After a L/G gravity extension, a maintenance action is required to reset the LGERS (For information on the L/G gravity extension, Refer to DSC-32-40-10-10 Landing Gear Gravity Extension).

FOR ROLLOUT : EXPECT ROLL INSTABILITY

When the wing landing gears are in an abnormal configuration, the trace of the remained landing gears (body lading gears) is narrow. Because of this landing gear configuration, the aircraft is unstable in roll for rollout and more sensible to lateral wind. For taxi, the flight crew should monitored the ground speed very carefully to avoid excessive taxi turn speed.

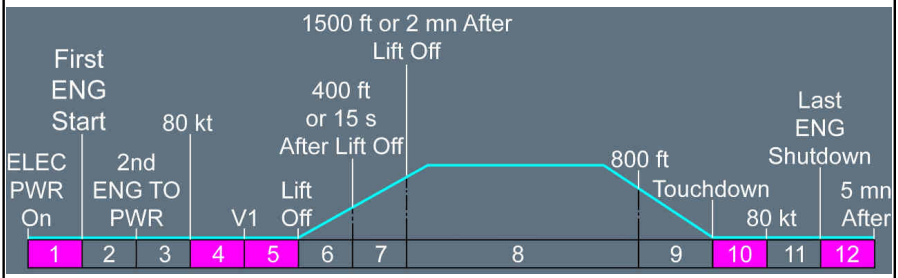
ADR pb

Flight Phase Inhibition:



Continued on the following page

NAV ADR 1+2+3 FAULT (Cont'd)

L2 If the alert triggers due to a triple “internal” ADR failure or because the three ADRS are OFF, the procedure requests to:

- Use Standby Flight Display (SFD) of the ISIS
- Set all ADR s to OFF to display the backup scales (i.e BUSS and GPS altitude) on the PFD .

If the alert triggers due to an anemometric failure detection on the three ADR s, the procedure request to:

- Apply immediate pitch attitude and thrust values
  These values allow safe flight conditions to be rapidly established in all flight phases (takeoff, climb, cruise) and aircraft configurations (weight and slats/flaps setting).
- Set all ADR s to OFF to display the backup scales (i.e BUSS and GPS altitude) available on the PFD .
- The SFD of ISIS may be reliable.

Note: *If the flight crew sets the three ADR s to OFF during an UNRELIABLE AIR SPEED INDICATION or an ALL AIR DATA DISAGREE procedure the NAV ADR 1+2+3 FAULT alert is inhibited.*

The flight control law reverts to direct law.
For more information on the backup scales *Refer to DSC-31-20-20-130-10 Backup Scales* .
For associated MEL dispatch conditions, *Refer to MEL/ME-ECAM-34-1 NAV ADR 1+2+3 FAULT* .

  RISK OF UNDUE OVERSPEED WARNING

NAV ALL AIR DATA DISAGREE
ALL AIR DATA REJECTED BY PRIMs

Applicable to: ALL

ANNUNCIATIONS

Triggering Conditions:

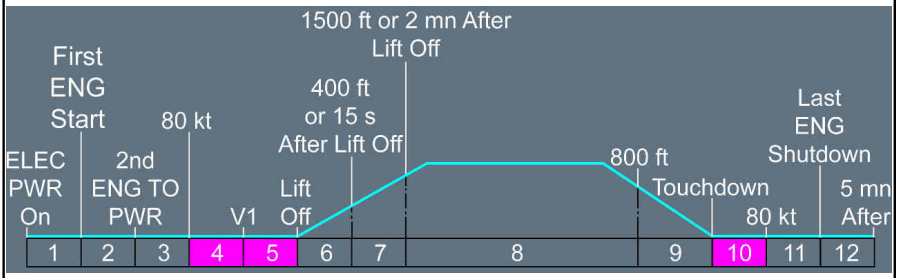
L2 The flight control computers detect that one air data parameter (e.g. CAS, Mach number, Static pressure) is not consistent between all air data sources (ADRs and ISIS), without being able to determine which air data source is unreliable.

Indications:

Audio

Master Light

Flight Phase Inhibition:



Continued on the following page

NAV ALL AIR DATA DISAGREE (Cont'd)

ALL AIR DATA REJECTED BY PRIMs

L2 The flight control computers reject erroneous speed or altitude source (ADR and/or ISIS) that provides a significant difference. However the NAV ALL AIR DATA DISAGREE alert triggers when the flight control computers are not able to identify the unreliable sources.
For more information on ADR monitoring by PRIM s *Refer to DSC-34-10-30-10-20 PRIM Monitoring* .
For more information on unreliable airspeed or altitude indications, *Refer to DSC-34-10-30-40 Unreliable airspeed or altitude indications* .
The flight control law reverts to direct law, and remain in direct law until the end of the flight.

The procedure includes the following main steps:

- Apply immediate pitch attitude and thrust values
  The flight crew must apply these immediate actions if safe conduct of the flight is impacted.
  The pitch attitude and thrust values allow safe flight conditions to be rapidly established in all flight phases (takeoff, climb, cruise) and aircraft configurations (weight and slats/flaps setting).
  In the mean time a quick troubleshooting may help determine whether or not one air data source (i.e. ADR or ISIS) is reliable.
- If no air data is reliable:
  - Below FL 250 : Switch off the three ADR s to display the backup scales on the PFD (i.e. BUSS and GPS altitude scale) and fly the green area of the speed scale
  - Above FL 250 : Fly pitch and thrust.

L23

Note: *At high altitude, most of unreliable airspeed situations are temporary phenomenons, and are caused by temporary contamination of the total pressure probes, with water or ice. Such temporary phenomenons, should disappear after a few minutes, allowing the recovery of the speed data.*
Because the PRIM s latches the rejection of the ADR s, only the speed data can be recovered. The direct law remains until the end of the flight. The flight crew cannot reconnect the AP s, and A/THR , until the end of the flight.

For more information on the backup scales (i.e. BUSS and GPS altitude), *Refer to DSC-31-20-20-130-10 Backup Scales* .
For associated MEL dispatch conditions, *Refer to MEL/ME-ECAM-34-1 NAV ALL AIR DATA DISAGREE* .

FMS POSITION / GPS PAGE.....SELECT

■ **Below FL 250 :**

AIR DATA (ADR s /STBY INSTR) ..... XCHECK

L2 *Crosscheck all speeds and altitudes indications.*

Alternates sources may be used to evaluate the air data:
- *GPS altitude*
- *GPS and IRS Ground Speeds, taking into account altitude and wind effect.*

L1 ■ **IF AT LEAST ONE AIR DATA IS RELIABLE:**

RELIABLE AIR DATA..... USE

Continued on the following page

NAV ALL AIR DATA DISAGREE (Cont'd)
ALL AIR DATA REJECTED BY PRIMs

■ **IF NO AIR DATA RELIABLE:**

ADR 1+2+3 P/B s ..... OFF

L2 *All ADR s must be switched off to replace the PFD 's normal speed scale and altitude indication by the backup speed scale and GPS altitude indication.*

L1 SPEED..... FLY THE GREEN

L2 *Fly within the green area of the speed scale to ensure safe flight.*
For slats/flaps retraction, it is recommended to fly at the top of the green area of the speed scale.
Before extending the slats/flaps, it is recommended to fly at the bottom of the speed scale green area, and to be in straight flight.

L1 SPD BRK : DO NOT USE

L2 *The BUSS is tuned for the aerodynamic model with the speed brake retracted. The speed brake extension must be avoided as it would affect the relation between Angle of Attack and airspeed, therefore making the BUSS unreliable.*

L1 ● **If at least two MFP heating are failed:**

AVOID ICING COND s

CABIN ALT MODE..... MAN

L2 *The flight crew manually controls the cabin altitude.*

L1

NAV UNRELIABLE AIR SPEED INDICATION

Applicable to: ALL

L2 Internal ADR monitoring or flight control computers monitoring automatically detect an unreliable airspeed situation. However depending on the monitoring threshold, the flight crew may be aware of an air data drift before any warning is triggered.
In such a situation, the flight crew can display this procedure by pressing the ECP ABN PROC pb , then selecting the NAV UNRELIABLE AIR SPEED INDICATION procedure.

Unreliable speed indications may be suspected by :
- Speed discrepancies (between ADR 1, 2, 3, and ISIS), or
- Fluctuating or unexpected increase/decrease/steady indicated speed, or pressure altitude, or
- Abnormal correlation of the basic flight parameters (speed, pitch attitude, thrust, climb rate), or
- Abnormal AP , FD , A/THR behavior, or
- OVERSPEED warnings or a F RELIEF ECAM message, that contradicts with at least one of the indicated speeds.
  Depending on the failure, the OVERSPEED warning may be false or justified. Buffet, associated with the OVERSPEED VFE warning, is a symptom of a real overspeed condition.

CAUTION	Always rely on the stall warning that could be triggered. It is not affected by unreliable speeds, because it is based on angle of attack.

- Inconsistency between radio altitude and pressure altitude, or
- Reduction in aerodynamic noise with increasing speed, or increase in aerodynamic noise with decreasing speed.

The content of the procedure is similar to the NAV ALL AIR DATA DISAGREE procedure:
- Apply immediate pitch attitude and thrust values
  The flight crew must apply these immediate actions if safe conduct of the flight is impacted.
  The pitch attitude and thrust values allow safe flight conditions to be rapidly established in all flight phases (takeoff, climb, cruise) and aircraft configurations (weight and slats/flaps setting).
  In the mean time a quick troubleshooting may help determine whether or not one air data source (i.e. ADR or ISIS) is reliable.
- If no air data is reliable:
  - Below FL 250 : Switch off the three ADR s to display the backup scales on the PFD (i.e. BUSS and GPS altitude scale) and fly the green area of the speed scale
  - Above FL 250 : Fly pitch and thrust.

Continued on the following page

NAV UNRELIABLE AIR SPEED INDICATION (Cont'd)

L23

Note: *At high altitude, most of unreliable airspeed situations are temporary phenomenons, and are caused by temporary contamination of the total pressure probes, with water or ice. Such temporary phenomenons, should disappear after a few minutes, allowing the recovery of the speed data.*

For more information on the backup scales (i.e. BUSS and GPS altitude), *Refer to DSC-31-20-20-130-10 Backup Scales* .

Continued on the following page

INFO

NO BLEED 1(2)(3)(4) AT LO ENG PWR

At low engine thrust settings, the air pressure from the IP stage is not sufficiently high: Therefore, no bleed is available from the affected engine.

AIR ENG BLEED TEMP LO

ON BLEED 1(2)(3)(4)

Applicable to: ALL

ANNUNCIATIONS

Triggering Conditions:

L2 In flight, engine bleed temperature is too low for wing deicing.

L3 The WING A-ICE pb is set to ON, and:

- One bleed supplies bleed air at a temperature lower than 150 °C, during more than 60 s, or
- Every 60 s, and during at least 9 min, the bleed air supplied to the wing anti-ice system, is below 150 °C .

Indications:

L2

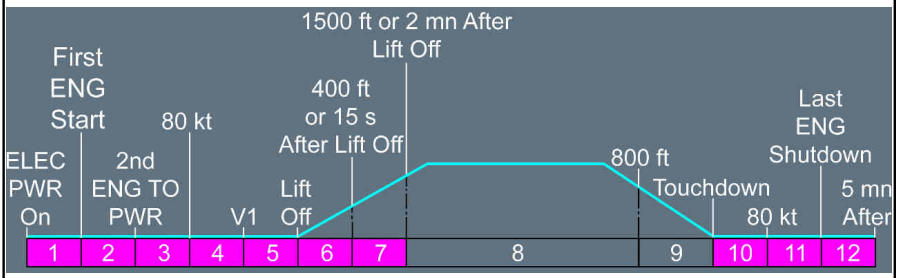
Audio

Master Light

SD page

BLEED SD Page

Flight Phase Inhibition:



Continued on the following page

AIR ENG BLEED TEMP LO (Cont'd)

ON BLEED 1(2)(3)(4)

L2 The temperature of the engine bleed air is too low for wing anti-ice.

When one bleed provides low temperature bleed air:
- The flight crew must increase the engine thrust.
- If the bleed continues to supply low temperature bleed air, the affected bleed is deficient, and the flight crew must switch off this bleed, provided that at least two bleeds remain operative.
  The temperature of the bleed air supplied to the wing anti-ice will increase.

When more than one bleed provide low temperature bleed air:
- The flight crew must increase the engine thrust.
- If the bleeds continue to supply low temperature bleed air, the flight crew must switch off the wing anti-ice system.

For associated MEL dispatch conditions, *Refer to MEL/ME-ECAM-36-21 AIR ENG BLEED TEMP LO* .

ENG THRUST..... INCREASE

L2 *The thrust lever of the affected engine must be increased, with the autothrust off. Low bleed temperature may be due to low outside air temperature: Therefore, increasing the engine thrust may increase the bleed air temperature, and clear the alert.*

Avionics Network

AVIONICS NETWORK ALL SWITCHES FAULT

Applicable to: ALL

ANNUNCIATIONS

Triggering Conditions:

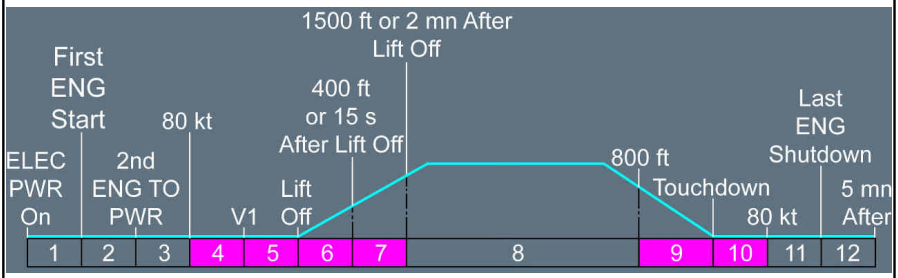
L2 All the switches of both avionics networks are failed: The aircraft systems can no longer communicate via the avionics networks.

Indications:

Audio

Master Light

Flight Phase Inhibition:



Continued on the following page

AVIONICS NETWORK ALL SWITCHES FAULT (Cont'd)

L2 When all switches are failed:

- Both FMS are no longer available.
- AP 1, and AP 2 are available. Only selected modes are available. AP 1 is also available for an ILS approach.
  - The GPS position of the aircraft, and ILS 1 remain available on the ISIS SND only.
  - NAVAIDS tuning is available via the RMP .
- Autothrust is inoperative.
- ADIRU 1, ADIRU 2, and ADIRU 3 remain available.
- Only the ECAM FUEL SD page is available on the SD display unit. The ECAM FUEL SD page is also displayed on both MFD display units. Therefore, the STATUS page is not available.

  On the ECAM FUEL SD page, the following indications remain available:
  - The FOB , and
  - The fuel quantity in every fuel tank.

  However, the precision of these indications, is degraded.
- On the PFD , the following indications are lost:
  - The Flight Director (FD)
    However, the Flight Path Vector(Velocity Vector) remains available on the PFD.
  - The FMA
  - The radio altitude indication. However, the autocallouts are available.
- The flight controls remain in normal law. However, the pitch and bank angle protections are indicated on the PFD, as in alternate law.
- The characteristic speeds are no longer displayed on the PFD speed scale. VMAX indicates only the VMO / MMO , whatever the aircraft configuration (landing gear or slats/flaps).
  The flight crew can use the speed placard, when the landing gear, or the slats/flaps are extended.
- Cabin pressure automatic regulation remains available. However, no information about the aircraft pressurization is available, and the landing field elevation has a default value fixed at 7 000 ft .
- Datalink communication is lost.
  ATC voice communication remains available. Voice communication tuning is available via the RMP .
- The transponder is available in mode A only: Altitude reporting is no longer available. The SQWK code can be modified via the RMP.

Continued on the following page

AVIONICS NETWORK ALL SWITCHES FAULT (Cont'd)

All the other surveillance functions are lost.

- Automatic fuel transfers, and jettison are no longer available. If an overweight landing is necessary, *Refer to PRO-ABN-ECAM-10-80-50 MISC OVERWEIGHT LDG* .
- CG position monitoring is not available: Flight time is limited to 4 hours.

During approach and landing

- Engine anti-ice remains available.
- Landing gear extension is available by gravity only.
- CAT 2 and CAT 3 approaches are no longer available.
  CAT 1 approach remains available.
- Normal and alternate braking are lost. Anti-skid is not available.
  Emergency braking remains available. The landing distance is increased.
- N/W and B/W steering are no longer available.

For associated MEL dispatch conditions, *Refer to MEL/ME-ECAM-42 AVIONICS NETWORK ALL SWITCHES FAULT* .

L2 The flight crew applies this procedure for any malfunction relative to the OIS (for e.g. OIT, keyboard, ACD, or laptop).

AFFECTED SIDE LAPTOP..... UNSTOW & VERIFY

L2 *Check that the laptop is still running.*

L3 *Move the cursor with the touchpad. If the cursor moves, consider the laptop is running.*

L1 ● **IF LAPTOP NOT AFFECTED:**

OIT (AFFECTED)..... OFF 5 S THEN ON

L2 *The OIT takes approximately 4 min to restart.*

L1 ● **IF NOT SUCCESSFUL AFTER 4 MIN:**

use laptop as rqrd

L2 *The onside laptop is still running and can be removed from its stowage and used directly on the sliding table, as required. Stow the laptop, before landing gear extension.*

L1 ● **IF LAPTOP AFFECTED:**

LAPTOP (AFFECTED).....OFF

L2 *To turn off the laptop, slide the laptop ON/OFF sw to the right for no more than 2 s.*

L1 ● **AFTER 30 S:**

LAPTOP (AFFECTED).....ON

L2 *The laptop takes approximately 5 min to restart.*

L1 ● **IF NOT SUCCESSFUL AFTER 5 MIN:**

use backup laptop as rqrd

L2 *Remove the backup laptop from its stowage for use on the sliding table, as required. Stow the laptop, before landing gear extension.*

APU

APU FAULT

Applicable to: ALL

ANNUNCIATIONS

Triggering Conditions:

L2 One of the following has occurred:
1. An APU emergency shutdown.

L3 An APU emergency shutdown will occur, if:
- The flight crew presses the APU FIRE pb, or
- The ground crew presses:
  - The APU SHUT OFF sw on the Maintenance nose gear panel, or
  - The APU EMER SHUT DOWN pb on the Refuel/Defuel panel.

L2 2. An APU automatic shutdown.

L3 An APU automatic shutdown will occur, in the case of :
- An aircraft emergency stop
- N1 overspeed: N1 is greater than 105 %
- N2 overspeed: N2 is greater than 102 %
- Low APU oil pressure
- Low generator oil pressure
- High APU oil temperature
- High generator oil temperature
- EGT limit exceeded: EGT is higher than 700 °C
- An ECB failure
- An APU fuel system failure
- Loss of normal DC power
- N1 underspeed: N1 is less than 88 %
- Loss of N1 or N2 overspeed protection
- Bleed air reverse flow

L2 3. The ECB detects a failure, but the APU is still available. In this case, neither an automatic nor emergency shutdown occurs.

ENG 1(2)(3)(4) FADEC FAULT (Cont'd)

L2 When the FADEC of the ENG 1(2)(3)(4) is failed, the FADEC cannot communicate via the avionic networks.
The FADEC can still provide engine control, and transmits to the EWD the primary engine parameters, N1 , current THR , maximum THR , thrust lever position, and EGT . The ENG 1(2)(3)(4) parameters on the ENG SD page are lost.
L3 The FADEC provides these parameters via Input/Output Modules that interface the FADEC and the avionic networks via conventional buses.
L2 If the ENG 1(2)(3)(4) oil pressure, LP compressor speed (N1), or HP compressor speed (N2) is abnormal, the ECAM can still trigger the associated ECAM alerts.
L3 The FADEC communicates with the FWS via conventional buses.
L2 For associated MEL dispatch conditions, *Refer to MEL/ME-ECAM-70-80-26 ENG 1(2)(3)(4) FADEC FAULT* .

● **If A/THR engaged :**
THR LEVER 1(2)(3)(4)..... MAN ADJUST

L2 *When the A/THR is used, adjust THR LEVER 1(2)(3)(4) in order to set the thrust (or N1) target to an average value, corresponding to the flight conditions. Continuous adjustment is not necessary.*

L1 ENG 1(2)(3)(4) PARAMETERS.....MONITOR

L2 *The essential ENG 1(2)(3)(4) parameters are still displayed on the EWD . Monitor these parameters in a standard way.*
The EGT is still normally displayed. However, the ENG 1(2)(3)(4) EGT OVER LIMIT ECAM will not trigger in the case of EGT exceedance. Therefore, the flight crew must closely monitor the EGT parameter of the ENG 1(2)(3)(4).

L1 ● **IF ABNORMAL :**
THR LEVER 1(2)(3)(4).....IDLE
ENG 1(2)(3)(4) MASTER.....OFF

ANNUNCIATIONS

Triggering Conditions:

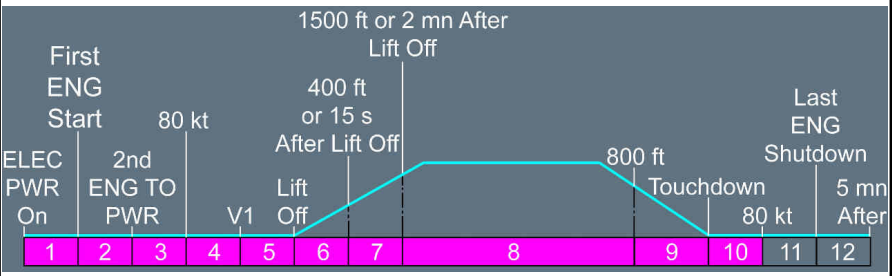
L2 The fuel filter is no longer monitored.

Indications:

Flight Phase Inhibition:



L2 For associated MEL dispatch conditions, *Refer to MEL/ME-ECAM-70-80-26 ENG 1(2)(3)(4) FUEL FILTER MONITORING FAULT* .

Crew awareness.

ENG 1(2)(3)(4) FUEL LEAK

Applicable to: ALL

ANNUNCIATIONS

Triggering Conditions:

L2 Detection of an abnormal fuel flow or fuel used on an engine.

L3 The detection is based on the following:
- comparison of the engine fuel flow and the average fuel flow of the three others. This will detects massive fuel leak after the fuel metering valve.
- comparison of the engine fuel used during 5 min and the average fuel used of the three others. This will detect unusual overconsumption.

L2 This is an indication of an internal engine fuel leak between the fuel flow transmitter and the combustion chamber.

Indications:

Audio

Master Light

APPR

BTV (If ENG 2(3) affected)
ENG 2(3) REVERSER (If ENG 2(3) affected)
CAT 3 DUAL (If APU off)

INFO

- If APU off:
  CAT 3 SINGLE ONLY
  Only three different generators supply the AC busbars. Therefore, CAT 3 DUAL is lost. The flight crew can recover CAT 3 DUAL by starting the APU. Therefore, the APU generator directly supplies the AC 1(2)(3)(4) busbar.

ENG 1(2)(3)(4) STALL

Applicable to: ALL

ANNUNCIATIONS

Triggering Conditions:

L2 The FADEC detects an engine stall.
A stall may be indicated by varying degrees of abnormal engine noises, accompanied by :
— flame from the engine exhaust (and possibly from engine inlet in severe cases),
— fluctuating performance parameters,
— sluggish or no thrust lever response,
— high EGT, and/or a rapid EGT rise when thrust lever is advanced.
Engine stalls must be reported for maintenance action.
ENG STALL alert is inhibited during the takeoff phase from V1 to 400 ft unless two or more engines are affected.
Indications:

Audio

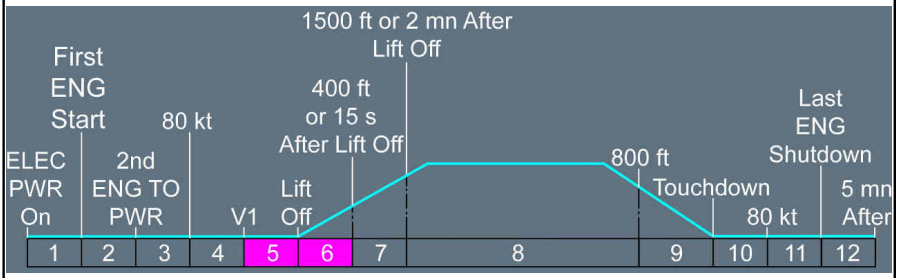
ENGINE SD Page

Flight Phase Inhibition:



Continued on the following page

ENG ALL ENG FLAME OUT (Cont'd)

This alert inhibits the ELEC EMER CONFIG alert.

The procedure is divided into two parts:
- Fuel remaining,
  Immediate actions then successive engine starts are attempted without and with APU bleed when available.
  If engine restarts are unsuccessful, forced landing or ditching procedure
- No fuel remaining,
  Immediate actions then forced landing or ditching procedure.

L2 **COMMUNICATIONS REMAINING WHEN THE AIRCRAFT IS ON BATTERIES ONLY.**

When the APU is not running and the RAT does not deliver electrical power due to low speed (approximately below 120 kt), the following communication means remain available:
- VHF 1
- RMP 1
- Audio controls on RMP 2 (Although RMP 2 display is black)
- ATC communication on both sides, and frequencies tuning on RMP 1 only
- All communications on both sides (PA, CAB and INT) whatever the devices.

ENG HI VIBRATIONS

Applicable to: ALL

ANNUNCIATIONS

Triggering Conditions:

L2 The flight crew can display this procedure by pressing the ECP ABN PROC pb, then selecting the ENG menu.

Indications:

SD page

ENGINE SD Page

Continued on the following page

ENG HI VIBRATIONS (Cont'd)

The ECAM vibration advisory (N1, N2 greater than 5 units) is mainly a guideline for the flight crew to more closely monitor engine parameters.
The ECAM vibration advisory does not necessarily require any engine shutdown.

Note:
- *High engine vibrations may be associated with cockpit and cabin smoke, and/or the smell of burning. This may only be due to the contact of the compressor blade tip with associated abradable seals.*
- *High N1 vibrations are generally associated with airframe vibrations. High N2 vibrations can occur without airframe vibrations.*

Check engine parameters and especially EGT. Crosscheck with other engines.

● **IF ICING CONDs:**

L2 An increase of N1 vibration in icing conditions, with or without engine anti-ice, may be due to fan blades and/or spinner icing.

L1 A/THR.....OFF
ALL ENGs (ONE BY ONE)..... IDLE THEN INCREASE

L2 *To shed ice, it may be necessary to perform several engine run-ups for approximately 6 min. During each engine run-up, increase thrust up to an appropriate setting for the flight phase. After each engine run-up, vibrations should decrease indicating the progress of the ice shedding.*
When the ice is shed, vibrations should return to normal and the flight crew can resume normal engine operation.

L1 ● **IF ABOVE VIB ADV:**
THRUST (AFFECTED ENG) .....REDUCE

L2 *If flight conditions permit, reduce THR to maintain vibration level below the advisory threshold.*

L1 ● **IF VIB STILL ABOVE VIB ADVI:**
ENG (AFFECTD) MASTER OFF..... CONSIDER

L2 *If the vibrations do not decrease, there may be other problems on the engine. Apply appropriate procedure.*

ENG RELIGHT IN FLIGHT

Applicable to: ALL

ANNUNCIATIONS

Triggering Conditions:

L2 The flight crew can display this procedure by pressing the ECP ABN PROC pb, then selecting the ENG menu.

Indications:

SD page

ENGINE SD Page

The procedure is divided into two parts, depending on the number of failed engines:

- If the start attempt applies to only one engine: The procedure enables to attempt either a windmilling start, or a starter-assisted engine relight with the bleed of the other engines
- If the start attempt applies to multiple engines: Similarly to the previous case, the procedure enables to attempt either a windmilling start, or a starter-assisted engine relight with the bleed of the other engines, but in addition the procedure covers engine relight using APU bleed, if available.

Continued on the following page

ENG RELIGHT IN FLIGHT (Cont'd)

- **FOR RELIGHT (SINGLE ENGINE):**

MAX GUARANTEED ALTITUDE : 30000 FT

MIN SPEED FOR WINDML RELIGHT : 260 KT

THR LEVER (AFFECTED)..... IDLE
ENG (AFFECTED) MASTER.....OFF
XBLEED..... OPEN
WING A-ICE.....OFF
FEED TK (AFFECTED ENG) MAIN PMP.....OFF

L2 *The standby pump of the feed tank starts when the flight crew switches off the associated main pump.*
If the engine failure was due to an undetected gravity feeding (e.g. main feed tank pump failed but not detected), the engine relights when the standby pump is running because the standby pump feeds again the engine with fuel.

L1 ENG START SEL.....IGN START

L2 - *The FADEC selects a starter assisted start (i.e. start valves automatically open), when N2 is below 11 %*
An airspeed at or above 260 kt ensures a windmilling start.

Continued on the following page

ENG TWO ENGS OUT ON SAME SIDE (Cont'd)

LAND ANSA

- **Depending on the failed engines:**
  PACK 1(2).....OFF

LDG PERF AFFECTED

- **If ENG 1+2 failed:**

  FOR TAXI : STEER ENDURANCE LIMITED

L2 *The normal Nose Wheel Steering (NWS) is lost. ALTN NWS is available.*
The ALTN NWS is designed to be used until the runway is cleared (i.e. to land and to exit the runway). Therefore, the flight crew should anticipate a tug to tow the aircraft back to the gate.

The flight crew should avoid a prolonged use of the ALTN NWS because it would result in:
- *An ALTN NWS overheat and the associated ECAM alert followed by*
- *A disconnection of the NWS.*

In alternate nose wheel steering:
- *The maximum steering rate is limited to 10 °/s (instead of 15 °/s for normal NWS)*
- *Damping of the CAPT and the F/O tillers is increased to prevent the flight crew from commanding excessive steering rates.*

Miscellaneous

MISC BOMB ON BOARD

Applicable to: ALL

INTRODUCTION

L2 The flight crew can display this procedure by pressing the ECP ABN PROC pb, then selecting the MISCELLANEOUS menu.

L1 IF POSSIBLE, LAND AND EVACUATE THE AIRCRAFT IMMEDIATELY.
If it is not possible to land and evacuate the aircraft within 30 minutes, apply the following procedure.

BACKGROUND

To avoid the activation of an altitude-sensitive bomb, the cabin altitude should not exceed the value at which the bomb has been discovered.
To reduce the effects of the explosion, the aircraft should fly as long as possible with approximately 1 PSI differential pressure, to help the blast go outwards. 1 PSI differential pressure corresponds to a 2500 feet difference between the aircraft and the cabin altitude. These conditions are achieved by using the manual pressure control.

PROCEDURE

The following procedures applies to cockpit, for cabin related procedures, *Refer to CCOM/14-90 Bomb On Board*.

The procedure assumes that it is initiated during climb or cruise :
- First, maintain the cabin altitude,
- While maintaining the cabin altitude, descend the aircraft to the cabin altitude +2 500 ftand maintain delta P at 1 PSI,
- During further steps of descent, maintain delta P at 1 PSI,
- For landing, reduce the differential pressure to zero, until the final approach.

If flight conditions are different, the crew should adapt the procedure, bearing in mind the above-mentioned principles (background paragraph).

  TRGT SPEED : PREFER LO IAS

L2 *Select the most appropriate speed, taking into account the time to destination, the fuel consumption and the fact that low speed could reduce the consequences of possible structural damage, if the bomb explodes*

L1 CABIN ALT MODE.....MAN

L2 *The purpose is to immediately prevent the cabin altitude from increasing, in order to avoid the activation of an altitude-sensitive bomb.*
The system automatically maintain the current cabin altitude.

L1 DESCENT TO CABIN ALT + 2500 FT / MEA

L2 *Descending to 2 500 ftabove the cabin altitude gives a cabin differential pressure of approximately 1 PSI, which helps to ensure that the blast goes outwards, if the bomb explodes.*

L1 - **WHEN ACFT ALT = CAB ALT + 2500 FT:**

  GALLEY.....OFF
  PAX SYS.....OFF

- **IF FUEL PERMITS:**

  Keep in mind that when flying at cabin altitude +2500ft, fuel consumption in CONF 1, with landing gear down, will be about 2.1 times that consumed in clean configuration.

  The detonation could damage the landing systems. Therefore, if fuel permits, configure the aircraft for landing as soon as possible.

  FLAPS..... AT LEAST CONF 1

L2 *For landing, use normal landing configuration.*

Applicable to: ALL

L2 The flight crew can display this procedure by first pressing the ECP ABN PROC pb, then by selecting the MISCELLANEOUS menu.

Continued on the following page

MISC CKPT WINDOW CRACKED (Cont'd)

L2 When a windshield or a lateral window is cracked, the flight crew must determine which layer is cracked (*Refer to DSC-56-10 Cockpit Windshields and Windows*).

L1 ■ **IF EXTERNAL LAYER CRACKED :**

(CRACKS ON EXT SIDE OF HEAT BARS)
STRUCTURE NOT AFFECTED
NO LIMITATION

L2 When the cracks are on the exterior side of the heat bars: Only the external layer is cracked. This layer is not a structural layer: The structure is not affected. The flight can be continued.

Windshield or window arcing is not likely to occur.

L1 ■ **IF INTERNAL LAYER CRACKED :**

(CRACKS ON CKPT SIDE OF HEAT BARS)
OR NO DIAGNOSIS POSSIBLE

L2 When the cracks are on the cockpit side of the heat bars: One structural layer is broken. The windshield, or window, is still able to withstand maximum differential pressure. However, because the flight crew is not able to accurately determine how many layers are cracked, the flight crew must reduce differential pressure to 5 PSI.

If the flight crew cannot determine which layer is cracked (external, or internal), the flight crew must reduce differential pressure to 5 PSI.

L1 MAX FL : 230/MEA

L2 *Reducing the flight level to FL 230 will enable the flight crew to obtain a differential pressure of 5 PSI. This reduction will also help to avoid excessive cabin altitude, and the triggering of the CAB PRESS EXCESS CAB ALT alert.*

L1 CABIN ALT MODE.....MAN
CABIN ALT TRGT.....AS RQRD

L2 Set the cabin altitude target, in accordance with the following table, to maintain a differential pressure of 5 PSI:

L1

ACFT FL	CABIN ALT TRGT
100	LDG ELEVN
150	3000
200	6000
230	8000

Continued on the following page

MISC CKPT WINDOW CRACKED (Cont'd)

L2 To avoid windshield or window arcing, turn off the heating:

L1 ■ **IF L WINDOW/WINDSHLD AFFECTED :**
AICU 1.....PULL

L2 The AICU 1 reset button is on the left reset panel of the overhead panel.

L1 This action will trigger the A-ICE CTL SYS FAULT .

■ **IF R WINDOW/WINDSHLD AFFECTED :**
AICU 2.....PULL

L2 The AICU 2 reset button is on the right reset panel of the overhead panel.

L1 This action will trigger the A-ICE CTL SYS FAULT .

ASSOCIATED PROCEDURES

A-ICE CTL SYS FAULT
Refer to procedure

Note: If the flight crew does not have enough visibility for approach due to windswhield(window) damage, they should consider automatic landing. If automatic landing is not available, consider opening the sliding window on the PF 's side, after cabin depressurization.

To manually depressurize the cabin:
- *Set the CABIN ALT MODE pb-sw to MAN*
- *Set the CABIN ALT TRGT selector to an altitude slightly above the current aircraft altitude*
- *Avoid high descend rate*
- *Open the sliding window on the PF 's side if the cabin ΔP equals 0 PSI .*

If the aircraft altitude is more than 10 000 ft , the flight crew should don the oxygen mask before cabin depressurization.
Due to increased noise level when the sliding window is open, the flight crew should pay particular attention to visual alerts.

MISC DITCHING

Applicable to: ALL

L2 The flight crew can display this procedure by first pressing the ECP ABN PROC pb, then by selecting the DITCHING procedure.

L1 The direction of ditching depends mainly on wind direction and sea state and these factors may be considered as follows:

1. Wind direction:
   This may be determined by observation of the waves, which move and break downwind. Spray from wave tops is also a reliable indicator.
2. Wind speed:

   The following guidelines can be used to evaluate wind speed:
   - A few white crests: 8 kt-17 kt
   - Many white crests: 17 kt-26 kt
   - Streaks of foam along water: 23 kt-35 kt
   - Spray from waves: 35 kt-43 kt.
3. Sea state:
   This is best determined from a height of 500 ft to 1 000 ft. At lower height, the direction of the swell may be less obvious than the direction of the waves, even though the waves are much smaller.
   When there is no swell, align into the wind.
   In the presence of swell, and provided that drift does not exceed 10 °, ditch parallel to the swell and as nearly into the wind as possible. If drift exceeds 10 °, ditch into wind. The presence of drift on touchdown is not dangerous, but every effort should be made to minimize roll.
   Touchdown with approximately 8 ° of pitch and minimum vertical speed.

MISC OVERWEIGHT LDG

Applicable to: ALL

L2 The flight crew can display this procedure by pressing the ECP ABN PROC pb, then selecting the MISCELLANEOUS menu.

Continued on the following page

MISC OVERWEIGHT LDG (Cont'd)

Automatic landing is certified up to the Maximum Landing Weight (MLW). Autoland flight tests have, however, been successful up to the Maximum Takeoff Weight (MTOW).
Depending on the situation (e.g emergency or other) and provided that the runway is approved for automatic landing, the flight crew can decide to perform an autoland up to the maximum takeoff weight.

JETTISON PROC..... CONSIDER

It is always possible to return immediately to land, at the departure runway, whatever the aircraft weight, provided that max reverse is used on at least one reverser.
On the other hand, the aircraft weight may be limiting, in case of an overweight landing on a diversion airport (depending on the airport altitude and OAT). In that case, either consider jettison to decrease the aircraft weight below the limiting weight , or choose another diversion.
It is not possible to jettison fuel from the feed tanks.

LDG DIST AFFECTED

Use the ECAM flap settings, if required, for abnormal operations.

In all other cases :
- *FULL is preferred for optimized landing performance, or*
- *If the aircraft weight is above one of the limiting weights, consider jettison and / or use FLAP 3 for landing.*
  In all cases, if the landing configuration is different from CONF FULL, use FLAP 1 for go-around.

Continued on the following page

MISC OVERWEIGHT LDG (Cont'd)

LIMITATIONS

LIMITATIONS ON ECAM

	APPR & LDG
	LDG DIST AFFECTED

L12

DEFERRED PROC

FOR APPROACH

PACK 1 + 2..... OFF OR ON APU BLEED

Selecting PACKS OFF (or supplied from APU) increases the maximum thrust available from the engines, in the case of a go-around.

IF LDG CONF 3 : USE CONF 1 FOR GO AROUND
TRGT SPEED AT RUNWAY THRESHOLD : VLS

This speed target is applicable in manual landing and autoland.
Reduce the speed to reach VLS at the runway threshold.
Touch down as smoothly as possible to reduce the V/S.
The maximum touch down V/S should not exceed 360 ft/min.
The main landing gears must touch down as symmetrically as possible.

LDG DIST COMPUTATION.....CONFIRM

FOR LANDING

USE MAX REVERSE ASAP
APPLY BRAKES AS NECESSARY

The flight crew may apply maximum braking after the nosewheel touchdown. But, if landing distance permits, they should delay or reduce the braking, to take full advantage of the available runway length.
If maximum braking is not necessary, it is recommended to use the BTV function, if available (i.e. there is no BTV failure, or no other failure that affects the landing performance), in order to optimize the braking.

MISC SEVERE TURBULENCE IN CRUISE

Applicable to: ALL

L2 The flight crew can display this procedure by first pressing the ECP ABN PROC pb, then by selecting the MISCELLANEOUS menu.

SIGNS.....ON

- **If no more restrictive speed limitation**

  MAX TURB SPEED : 300 / .85

L2 *This speed range:*
- *Protects the aircraft structure from wind gusts*
- *Maintains a buffet margin, especially during vertical wind gusts.*

L1 MIN TURB SPEED : GREEN DOT
ADJUST SPEED AS NECESSARY FOR COMFORT
AP : KEEP ON
CABIN & CKPT (LOOSE EQPT)..... SECURE

L2 *The flight and cabin crewmembers must secure all loose equipment.*

L1 SPEED BRAKES..... AS RQRD

L2 *Be prepared to use the speedbrakes, if necessary.*

L1
- **IF THRUST VARIATIONS BECOME EXCESSIVE:**

  A/THR..... DISCONNECT

L2 *Do not attempt to maintain Mach or airspeed.*

MISC VOLCANIC ASH ENCOUNTER

Applicable to: ALL

L2 The flight crew can display this procedure by first pressing the ECP ABN PROC pb, then by selecting the MISCELLANEOUS menu.

Continued on the following page

MISC VOLCANIC ASH ENCOUNTER (Cont'd)

180° TURN.....INITIATE

L2 *The performance of a 180 ° turn will usually enable the aircraft to exit the volcanic ash clouds as quickly as possible, because volcanic ash clouds can extend for hundreds of nautical miles.*

L1 ATC.....NOTIFY

A/THR..... OFF

L2 *This action prevents thrust variations due to the use of autothrust.*

L1 THRUST (IF CONDS PERMIT)..... REDUCE

L2 *A decrease in thrust helps to maintain the engine stall margin by reducing the amount of volcanic ash ingestion and limiting the EGT . It also limits the accumulation of molten ash on the turbine vanes.*
Do not climb, because this increases the EGT .

L1 CREW OXY MASKS..... ON / 100% / EMER

CABIN CREW.....ADVISE

PAX OXY MASK MAN ON.....AS RQRD

L2 *Oxygen masks may be necessary depending on the cabin contamination.*

L1 ENG A-ICE.....ON

WING A-ICE.....ON

AIR FLOW.....HI

L2 *Maximum air bleed provides the engines with an additional stall margin.*

L1 *Note: If a CARGO VENTILATION system is installed, the flight crew should turn off the CARGO ISOL VALVES pb-sw to prevent the ECAM from triggering a cargo smoke warning.*

APU.....AS RQRD

L2 *It may be necessary to turn on the APU for a starter–assisted engine relight.*

L1 ENG PARAMETERS..... MONITOR

L2 *Carefully monitor the EGT to prevent the engines from exceeding EGT limits.*

Note: To prevent the engines from exceeding EGT limits, it may become necessary to perform a precautionary engine shutdown. In this case:
- *Restart the engines, when the aircraft is no longer flying in a volcanic ash cloud*
- *The engines may accelerate very slowly. This is not an indication of a start failure*
- *Due to the fact that the compressor and turbine blades may have been eroded, avoid sudden thrust changes. Fuel flow and the EGT may increase.*

L1 AIR SPEED.....MONITOR

Continued on the following page

MISC VOLCANIC ASH ENCOUNTER (Cont'd)

L2 *Volcanic ash may cause a blockage in the pitot probes. If speed indication is lost, or becomes unreliable, Refer to NAV ALL AIR DATA DISAGREE and apply the procedure.*

Note: Electrostatic conditions may cause communication problems.

L1 *Note: If the flight crew does not have enough visibility for approach due to windshield (window) damage, they should consider automatic landing. If automatic landing is not available, consider opening the sliding window on the PF 's side, after cabin depressurization.*

To manually depressurize the cabin:

- *Set the CABIN ALT MODE pb-sw to MAN*
- *Set the CABIN ALT TRGT selector to an altitude slightly above the current aircraft altitude*
- *Avoid high descend rate*
- *Open the sliding window on the PF 's side if the cabin ΔP equals 0 PSI .*

If the aircraft altitude is more than 10 000 ft , the flight crew should don the oxygen mask before cabin depressurization.
Due to increased noise level when the sliding window is open, the flight crew should pay particular attention to visual alerts.

Intentionally left blank

Introduction

INTRODUCTION

Applicable to: ALL

OVERVIEW

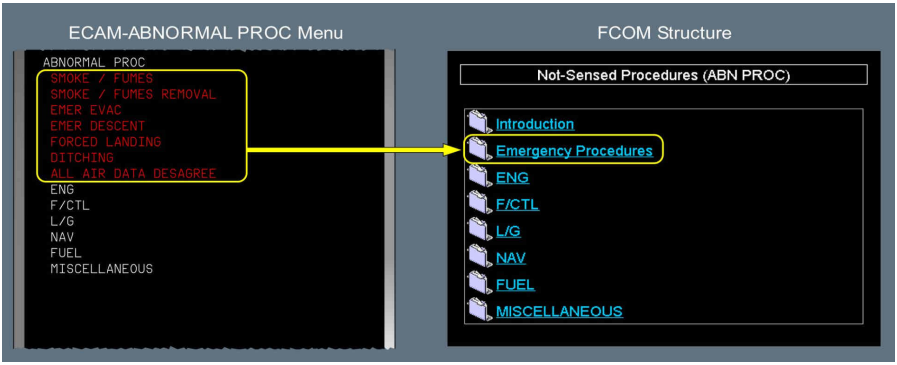
Not-sensed procedures are abnormal and emergency procedures that appear on the ECAM , and that the flight crew manually activates. Not-sensed procedure also refers to as not-sensed ABN PROC . For more information, *Refer to DSC-31-40-10-00001135 Sensed and Not-Sensed Procedures* .

When the flight crew performs not-sensed ABN PROC , the flight crew uses the “READ” and “DO” principle (oral reading). For more information, *Refer to PRO-ABN-00 Operational Recommendations* .

PRESENTATION OF THE NOT-SENSED ABN PROC IN THE FCOM

Not-sensed procedures (ABN PROC) in the FCOM enable the flight crew to consult all the not-sensed ABN PROC , that appear on ECAM . They appear in the FCOM in the same way as on the ECAM . However, for the sole purpose of the FCOM consultation, all the emergency procedures that appear on the first part of the ECAM ABN PROC menu, are grouped in a single subchapter "Emergency Procedures" in the FCOM as illustrated below.

Not-Sensed ABN Procedure Presentation



Not-sensed procedures (ABN PROC) section only provides links to the Abnormal and Emergency Procedures section in order to enable the flight crew to quickly access the description of the not-sensed ABN PROC .

ENGINE FAILURE AFTER V1 - CONTINUED TAKEOFF

Applicable to: ALL

L2 The following procedure applies, in the case of an engine failure:

- On ground, after V1:
  Continue the takeoff.
- During the initial climb-out.

Continued on the following page

ENGINE FAILURE AFTER V1 - CONTINUED TAKEOFF (Cont'd)

L2 For additional training-oriented information, *Refer to FCTM/AO-20-10-3 Aircraft Handling.*

L1 **AFTER V1**

TAKEOFF.....CONTINUE
DIRECTIONAL CONTROL.....USE RUDDER

L2 *Use rudder as usual, to stay on the runway centerline.*

L1 **AT VR**

ROTATION.....PERFORM

L2 *At VR, initiate the rotation towards a pitch attitude of 10 °.*
After liftoff, follow the SRS pitch command bar.

L1 MIN SPEED.....V2

L2 *If an engine failure occurs on ground, the SRS takes the engine failure into account, and targets V2 speed (instead of V2+10 kt with all engines operating).*
If an engine failure occurs after liftoff, the SRS takes the engine failure into account, and targets the speed at which the failure occurred (limited between V2 and V2+15 kt).

L1 **BEFORE THRUST REDUCTION ALTITUDE**

CAUTION	TOGA is permitted for only 10 min.

L2 Perform the following procedure to ensure that the directional control is correctly managed, when the aircraft is in climb.

L1 ● **When in positive climb:**
LDG GEAR.....UP
BETA TARGET.....CENTER

L2 *Shortly after liftoff, the PFD displays the beta target indication. Adjust the rudder position to center the beta target.*

L1 THRUST..... AS APPROPRIATE

L2 - *On FLEX takeoff, TOGA application may restore thrust margins.*
- *On derated takeoff, do not use TOGA thrust, if the speed is below F in CONF 2 and 3.*

L1 ● **When convenient:**
RUDDER TRIM.....SET

REJECTED TAKEOFF (Cont'd)

PROCEDURE

L12

CAPT	F/O
"STOP"..... ANNOUNCE	
Simultaneously:	
THRUST LEVERS..... IDLE	
REVERSE THRUST..... MAX AVAIL	REVERSES..... CHECK/ANNOUNCE (1)
	DECELERATION..... CHECK/ANNOUNCE (2)
	ANY AUDIO.....CANCEL
AIRCRAFT STOPPED:	
Consider positioning the aircraft to keep any possible fire away from the fuselage.	
REVERSERS..... STOWED	ATC.....NOTIFY
PARKING BRAKE..... ON	EMER EVAC Procedure (QRH)..... LOCATE
CABIN CREW.....ALERT	
ECAM ACTIONS.....ORDER	ECAM ACTIONS.....PERFORM
The aircraft should remain stationary while the flight crew evaluates the situation.	
EVACUATION PHASE:	
•If required:	ATC.....NOTIFY
EMER EVAC Procedure.....APPLY	*The flight crew should notify the ATC of their intention, and the required assistance.*
For more information on the EMER EVAC procedure, Refer to PRO-ABN-ECAM-10-80-10 EMER EVAC .	
Except if the emergency evacuation procedure is within the ECAM procedure of the failure, the flight crew should apply the not-sensed emergency evacuation procedure on the ECAM or the QRH procedure, as appropriate.	

(1) Full reverse may be used until the aircraft is fully stopped. But, if there is enough runway at the end of the deceleration, the flight crew should reduce the reverse thrust when passing 70 kt .

(2)

- *If the brake response does not seem appropriate for the runway condition, the flight crew should apply and maintain full manual braking.*
  If the flight crew has any doubt, they must take over manually.
  Before clearing the runway, the flight crew must ensure that an evacuation is not necessary and that it is safe.
- *If the autobrake is inoperative, the Captain simultaneously reduces the thrust and applies maximum pressure on both pedals. The aircraft stops in the minimum distance, only if the flight crew maintains the brake pedals fully pressed until the aircraft stops.*
- *If the normal braking is inoperative, the flight crew should immediately apply the LOSS OF BRAKING procedure (Refer to PRO-ABN-NECA-32-130 LOSS OF BRAKING).*
- *After a rejected takeoff, if the aircraft stops using autobrake RTO, before taxiing, the flight crew must disarm the ground spoilers in order to release the brakes.*
- *If the takeoff is rejected before 72 kt , the ground spoilers do not extend, and the auto-brake is not active.*

STALL RECOVERY

Applicable to: ALL

As soon as any stall indication (could be aural warning, buffet, etc.) is recognized, apply the immediate actions:

NOSE DOWN PITCH CONTROL..... APPLY

This will reduce angle of attack.

Note: In the case of lack of pitch down authority, reducing thrust may be necessary.

BANK..... WINGS LEVEL

- **When out of stall (no longer stall indications):**

THRUST.....INCREASE SMOOTHLY AS NEEDED

Note: In the case of one engine inoperative, progressively compensate the thrust asymmetry with rudder.

SPEEDBRAKES.....CHECK RETRACTED

FLIGHT PATH..... RECOVER SMOOTHLY

- **If in clean configuration and below 20 000 ft:**

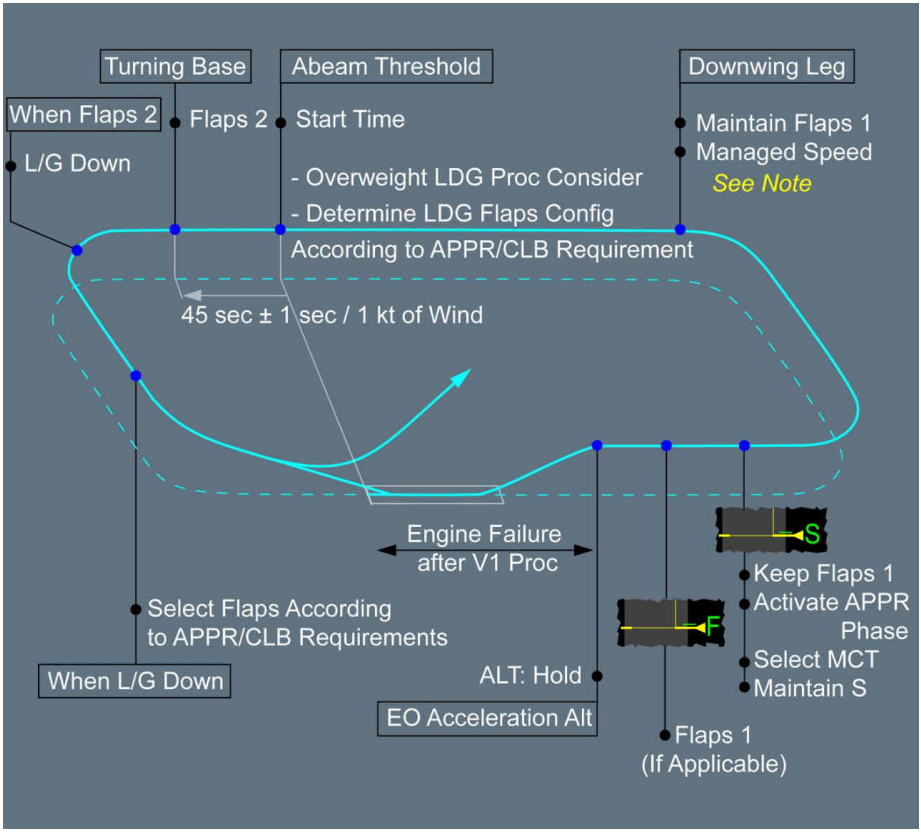
FLAP 1..... SELECT

Note: If a risk of ground contact exists, once clearly out of stall (no longer stall indications), establish smoothly a positive climb gradient.

VMC LANDING FOLLOWING ENGINE FAILURE AT TAKEOFF

Applicable to: ALL

VMC Landing After Engine Failure at Takeoff



Continued on the following page

VMC LANDING FOLLOWING ENGINE FAILURE AT TAKEOFF (Cont'd)

Note: *This pattern takes into account the use of managed speed (including minimum ground speed function).*

If managed speed is not used, manually select the following speeds:
- *F, after Flaps 2 selection*
- *VAPP, after landing flaps selection.*

If the flight plan is not updated with the new runway, use the selected speed.

Intentionally left blank

FLIGHT CREWMEMBER INCAPACITATION

Applicable to: ALL

If a flight crewmember is incapacitated, the other flight crewmember(s) in the cockpit, must request assistance from the cabin crew as soon as possible. The flight crewmember(s) that is(are) not incapacitated can use the PA system to call the cabin crew by announcing, for example: “Attention, Purser to the cockpit please”.

The Purser, or another cabin crewmember, must immediately go to the cockpit, and perform the following actions:

- Tighten, and manually lock the shoulder harness of the incapacitated flight crewmember
- Adjust the incapacitated flight crewmember’s seat to the most backward and reclined position.

The removal of the incapacitated flight crewmember from the cockpit seat requires the assistance of two people, in order to ensure that during this course of this action, no pushbuttons, switches and/or controls in the cockpit are inadvertently operated.
If it is not possible to remove the incapacitated flight crewmember from their seat, one cabin crewmember must remain in the cockpit, in order observe and take care of this incapacitated flight crewmember.

In coordination with the Purser, the flight crewmember(s) that is(are) not incapacitated, must try to find, and request assistance from, any passenger that has:

- Medical qualifications, and is able to provide medical assistance
- A commercial pilot typerating, and is able to perform the duties of the incapacitated flight crewmember.

Intentionally left blank

AUTOLAND

Applicable to: ALL

ANNUNCIATIONS

Triggering Conditions:

L2 The aircraft is in autoland below 200 ft RA, and one of the following occurs:

- The last AP disengages

L3 The AUTOLAND light stops flashing, when:

- The flight crew engages the go-around, or
- The altitude goes above 200 ft RA, or
- The flight crew cancels the AUTO FLT AP OFF alert (if the alert was triggered).

L2 *Note: If the flight crew quickly presses on the sidestick pushbutton two times, the AUTOLAND light appears furtively.*

- Above 100 ft RA, during a CAT 2 or CAT 3 ILS approach, or during a GLS CAT 1 approach with Autoland:
  - The glide signal of the ILS transmitter fails, or
  - The glide signal of the GLS transmitter fails, or
  - The glide deviation is excessive.

  L3 The glide deviation becomes excessive, when the glide deviation is one gradation away from the center of the scale.

  L2 The AUTOLAND light stops flashing, when:
  - LAND disengages, or
  - The flight crew disengages the AP(s) by pressing the sidestick pushbutton two times.
- Above 15 ft RA, during a CAT 2 or CAT 3 ILS approach, or during a GLS CAT1 approach with Autoland:
  - The LOC signal of the ILS transmitter fails, or
  - The LOC signal of the GLS transmitter fails, or
  - The LOC deviation is excessive.

  L3 The LOC deviation becomes excessive, when the LOC deviation is one quarter gradation away from the center of the scale.

  L2 The AUTOLAND light stops flashing, when:
  - LAND or FLARE disengages, or
  - The flight crew disengages the AP(s) by pressing the sidestick pushbutton two times.
- One radio altimeter is failed, and the values provided by the two remaining radio altimeters differ by more than 15 ft

Continued on the following page

AUTOLAND (Cont'd)

The AUTOLAND light stops flashing, when:
- LAND, FLARE or ROLL OUT disengages, or
- The flight crew disengages the AP(s) by pressing the sidestick pushbutton two times.

- A long flare is detected.

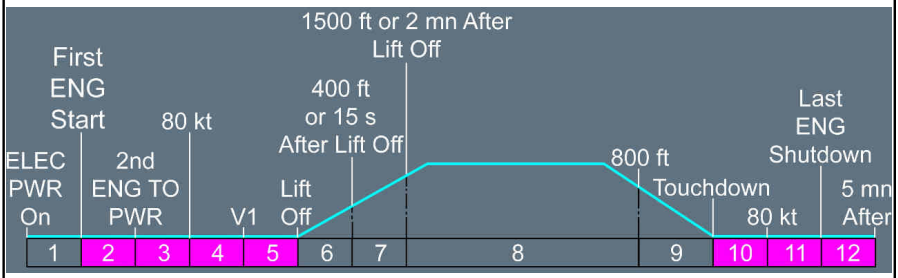
L3 A long flare is detected, when FLARE is engaged for 13 s.

L2 The AUTOLAND light stops flashing, when:
- The flight crew engages the go-around, or
- The flight crew disengages the AP(s) by pressing the sidestick pushbutton two times.

Indications:

Local light

Flight Phase Inhibition:



GO-AROUND.....PERFORM

In some cases, if visual references are sufficient, a manual landing can be performed.

FIRE SMOKE / FUMES REMOVAL

Applicable to: ALL

L2 The flight crew can display this procedure by first pressing the ECP ABN PROC pb.
Apply the SMOKE / FUMES REMOVAL paper procedure, if smoke / fumes become the greatest threat while applying the SMOKE / FUMES paper procedure.

The procedure is divided in three parts:
- Cockpit affected,
- Cockpit not affected and upper deck affected,
- Cockpit not affected and main deck affected.

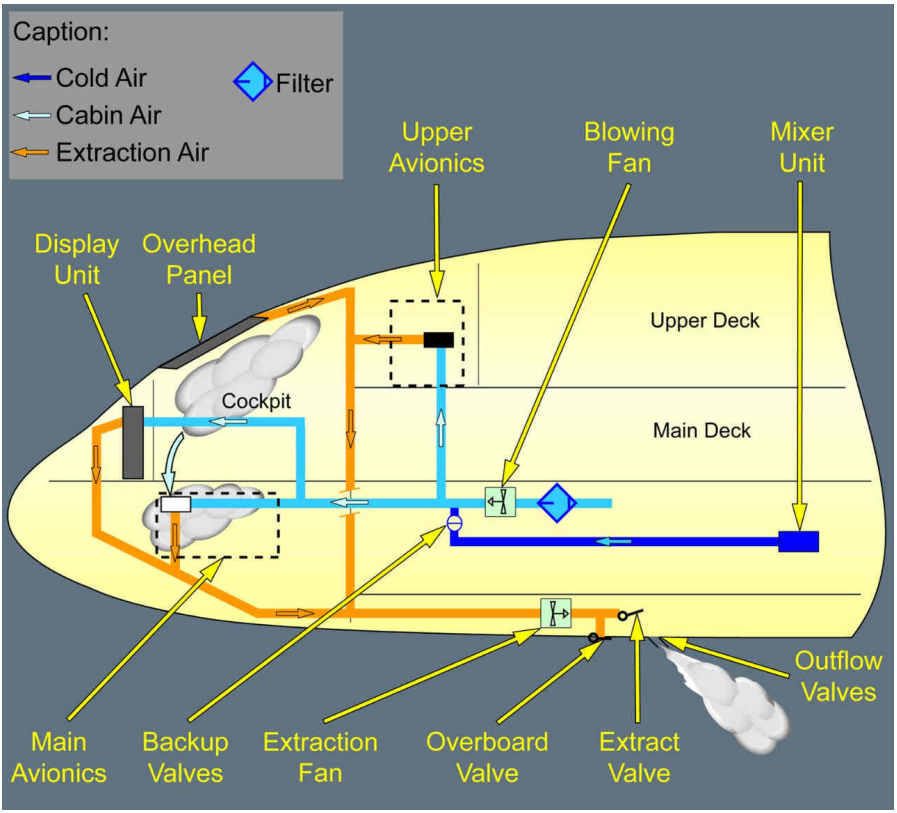
COCKPIT AFFECTED

The smoke is initially evacuated from the cockpit via the forward outflow valve using the avionics ventilation extraction fan.

Continued on the following page

FIRE SMOKE / FUMES REMOVAL (Cont'd)

Air Flow for Cockpit Smoke Removal



Descent is initiated to FL 100 or Minimum En-route Altitude.

Continued on the following page

FIRE SMOKE / FUMES REMOVAL (Cont'd)

At FL 100 the RAM AIR is open to supply fresh air to the cabin following packs closure.
If smoke continues, PM cockpit window is opened.

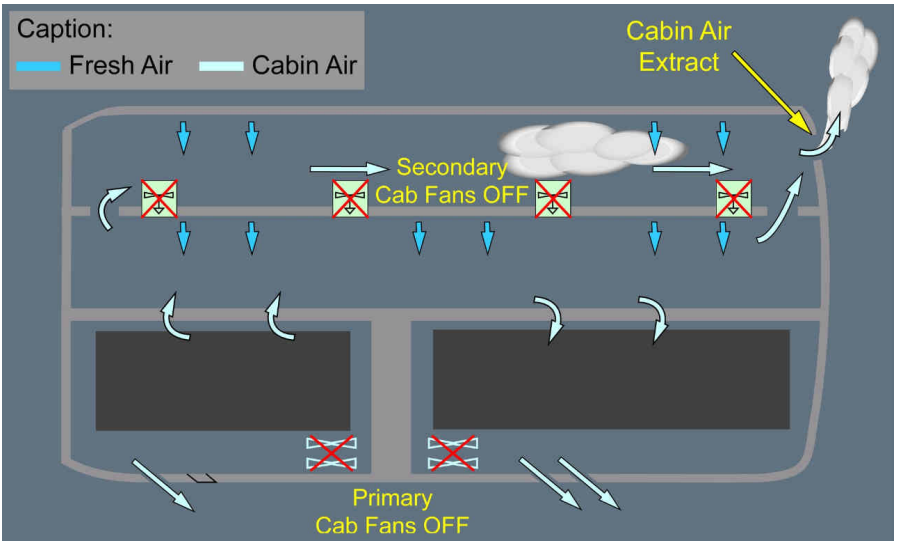
COCKPIT NOT AFFECTED AND UPPER DECK AFFECTED

The smoke is evacuated from the upper deck via the CABIN AIR EXTRACT valve located at the rear of the upper deck.
CABIN ALT MODE and CABIN V/S must be AUTO in order to ensure the automatic closure of one forward outflow valve. This shall ensure that main deck is not contaminated with air from the upper deck.

Continued on the following page

FIRE SMOKE / FUMES REMOVAL (Cont'd)

Air Flow for Upper Deck Smoke Removal



COCKPIT NOT AFFECTED AND MAIN DECK AFFECTED

Smoke is evacuated from the main deck via the outflow valves.

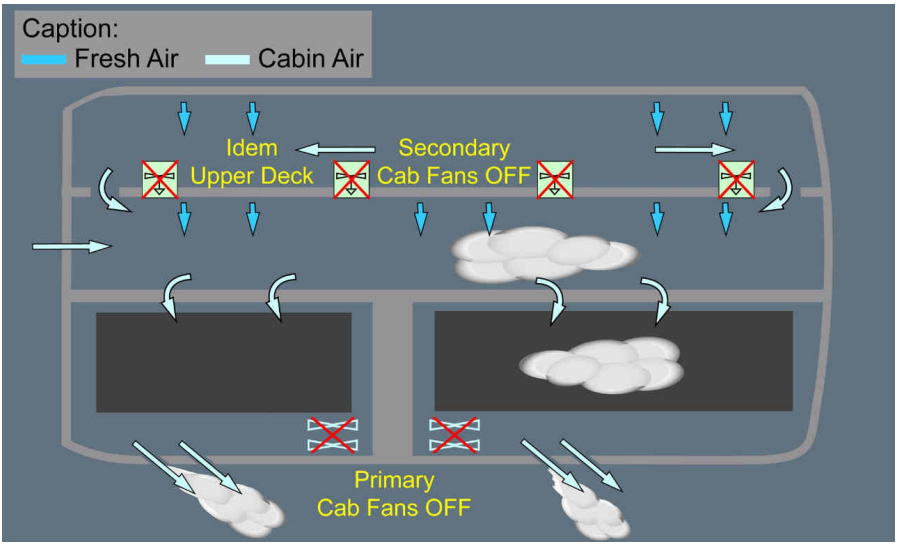
Avionics ventilation is evacuated using the overboard valve (VENT AVNCS EXTRACT OVRD), this will decrease the amount of air extracted from the cockpit and thus build up an

Continued on the following page

FIRE SMOKE / FUMES REMOVAL (Cont'd)

overpressure in the cockpit. This shall prevent smoke entering the cockpit from the main deck.

Air Flow for Main Deck Smoke Removal



Continued on the following page

FIRE SMOKE / FUMES REMOVAL (Cont'd)

EMER EXIT LT ..... ON
AIR FLOW.....HI

L2 *This will provide maximum airflow from the packs. Do not shut down the air conditioning packs, and do not reduce ventilation in an attempt to smother the fire.*

Do not deploy oxygen masks, if fire is suspected in the cabin.

L1 ATC.....NOTIFY FOR DESCENT
DESCENT (FL 100 or MEA OR minimum obstacle clearance altitude).....INITIATE

- **If cockpit affected :**

  ALL CARGO ISOL VALVES.....OFF
  CABIN ALT MODE.....MAN
  CABIN ALT TRGT..... 10000 FT/MEA
  CABIN V/S MODE..... MAN
  CABIN V/S TRGT..... 1000 FT/MIN

Continued on the following page

FIRE SMOKE / FUMES REMOVAL (Cont'd)

L2 *Descent is initiated to FL 100, or the MEA, or the minimum obstacle clearance altitude, while the cabin altitude is increased to 10 000 ft or the MEA.*

The increase in cabin altitude also reduces, at least temporarily, the smoke concentration.

Cabin depressurization starts, when descent is initiated.

Passenger oxygen, as required by regulations

L1 SMOKE/FUMES/QRH PROC.....CONTINUE

L2 *While descending, continue applying the appropriate steps of the SMOKE/FUMES paper procedure depending on the suspected smoke source. When reaching FL 100/MEA continue the SMOKE REMOVAL procedure.*

L1 ● **At FL 100/MEA :**

PACK 1+2..... OFF

Continued on the following page

FIRE SMOKE / FUMES REMOVAL (Cont'd)

L2 *Packs must be switch off to allow cockpit window opening.*

L1 RAM AIR.....ON

L2 *At FL 100, or MEA, it is possible to open the RAM AIR valve, when Delta P is 1 PSI psi or below.*
RAM AIR does not assist smoke removal, but allows to supply cabin with fresh air when both packs are OFF.

L1 ● **If smoke continues :**

L2 During descent, the SMOKE / FUMES procedure has been applied, if smoke generation has stopped it may not be necessary anymore to open the cockpit window.

L1 MAX SPEED : 230 KT
CKPT DOOR OR DOOR FLAP.....OPEN
HEADSETS.....ON

Continued on the following page

FIRE SMOKE / FUMES REMOVAL (Cont'd)

CKPT WINDOW (PM).....OPEN | PNF

- **When window is open :**

  PACKS (NOT AFFECTED).....ON

  VISUAL WARNING (noisy cockpit).....
  .....MONITOR

L2 *Due to the increased noise level, pay particular attention to visual warnings.*

L1 SMOKE/FUMES/QRH PROC.....
.....CONTINUE

L2 *Continue applying the appropriate steps of the SMOKE / FUMES paper procedure depending on the suspected smoke source.*

L1 - **If cockpit not affected and only UPPER deck affected :**

  CABIN ALT MODE.....AUTO

  CABIN V/S MODE..... AUTO

  CABIN AIR EXTRACT.....OVRD

Continued on the following page

FIRE SMOKE / FUMES REMOVAL (Cont'd)

L2 *The CABIN AIR EXTRACT opens, one forward outflow valve closes and the other outflow valves open.*

This ensures that main deck is not contaminated with air from the upper deck.

L1 SMOKE/FUMES/QRH PROC.....CONTINUE

L2 *Continue applying the appropriate steps of the SMOKE / FUMES paper procedure depending on the suspected smoke source.*

L1 ● **If cockpit not affected and only MAIN deck affected :**

VENT AVNCS EXTRACT.....OVRD

L2 *This pressurizes the cockpit, and prevents contaminated air from the main deck to enter the cockpit.*

L1 ALL CARGO ISOL VALVES.....OFF

SMOKE/FUMES/QRH PROC.....CONTINUE

Continued on the following page

FIRE SMOKE / FUMES REMOVAL (Cont'd)

L2 *Continue applying the appropriate steps of the SMOKE / FUMES paper procedure depending on the suspected smoke source.*

FIRE SMOKE/FUMES

Applicable to: ALL

L2 This procedure is a paper procedure of the Quick Reference Handbook (QRH).

It includes all the steps of the following ECAM procedures:
- SMOKE L(R) UPPER AVNCS SMOKE
- SMOKE L(R) MAIN AVNCS SMOKE
- SMOKE AFT AVNCS SMOKE
- FIRE SMOKE/FUMES not-sensed procedure.

Apply this paper procedure when :
- The flight(cabin) crew suspects that smoke is coming from the avionics, and/or the air conditioning, and/or the cabin equipment, or
- Requested by one of the ECAM AVNCS SMOKE procedures, or
- There is a smell of smoke/fumes :
  - If the smell is similar to that of orange peels, suspect a toxic leak of rain repellent fluid
  - If the smell is similar to that of pine needles, suspect a non-toxic leak.

If any other ECAM SMOKE alert triggers, e.g. CARGO SMOKE, the flight crew must first apply the ECAM procedure and then consider applying this paper procedure.
These ECAM SMOKE alerts may be caused by another source, that the flight crew, the cabin crew or an avionics smoke detector should usually detect first.

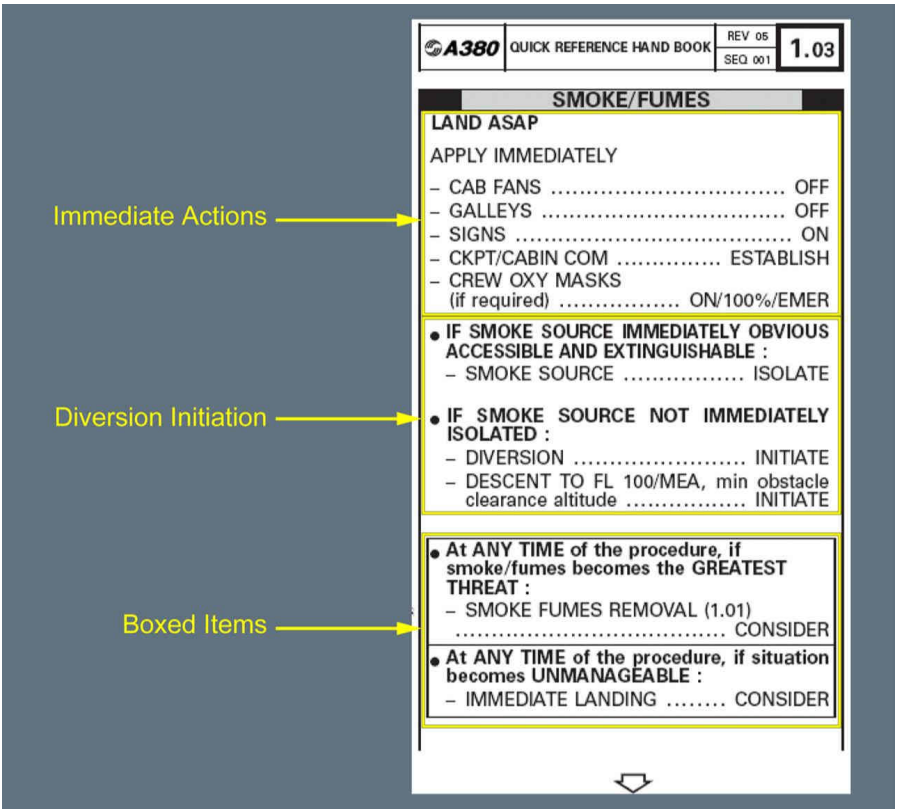
PROCEDURE LAYOUT

The first page of the QRH procedure contains the following main steps:

Continued on the following page

FIRE SMOKE/FUMES (Cont'd)

Procedure Layout



IMMEDIATE ACTIONS

The procedure lines above the boxed items indicate the immediate actions that the flight crew must perform, if smoke is detected (with or without ECAM activation, and regardless of the smoke source). These immediate actions correspond to the most common steps to apply in smoke cases.

The not-sensed ECAM FIRE SMOKE/FUMES procedure, and the ECAM AVNCS SMOKE procedures include the immediate actions and refer to the QRH procedure for further actions, if any.

Continued on the following page

FIRE SMOKE/FUMES (Cont'd)

DIVERSION INITIATION

In parallel, the flight crew must also be prepared to immediately perform a diversion. However, this diversion may be avoided if the smoke source is obvious, accessible and extinguishable or confirmed isolated (after completion of the immediate actions).

BOXED ITEMS

The boxed items indicate the actions that the flight crew must consider, if at any time during the remainder of the procedure but always after the initial steps :
- Smoke/fumes become the greatest threat and smoke/fumes removal is required, and/or
- The situation becomes critical and can no longer be controlled.

PROCEDURE LAYOUT (CON'T)

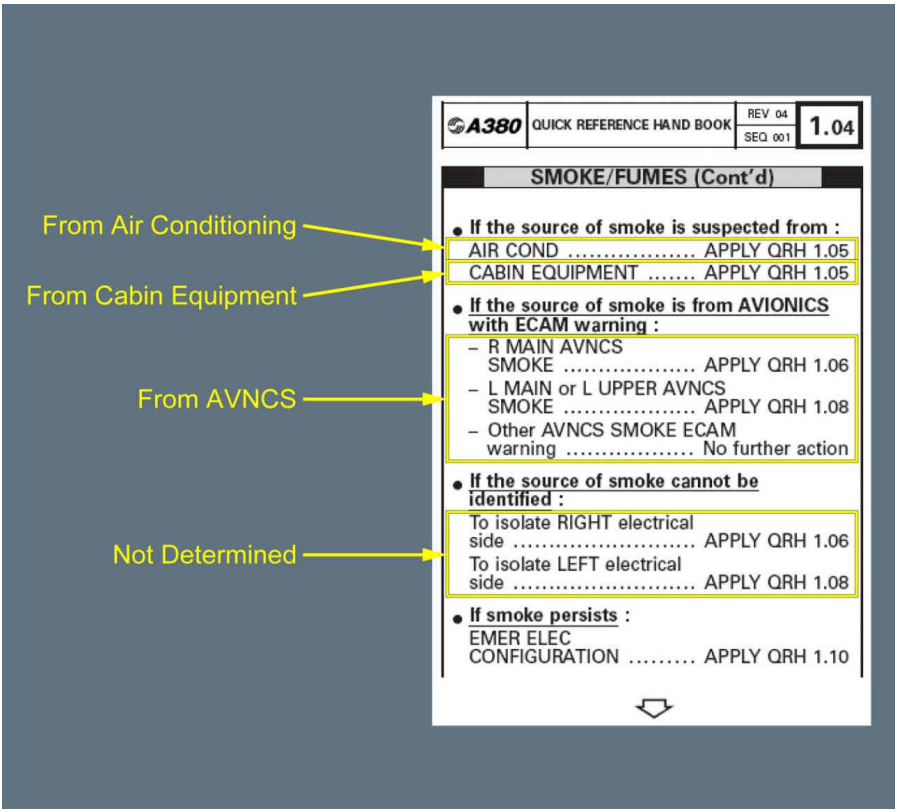
The procedure lines below the boxed items indicate the actions that the flight crew must perform, as soon as they suspect a source of smoke.

The actions will depend on whether the smoke is coming from:
- Air conditioning, or
- Cabin equipment, or
- Avionics, or
- Smoke source cannot be determined and still continues.

Continued on the following page

FIRE SMOKE/FUMES (Cont'd)

Procedure Layout (Con't)



SMOKE FROM AIR CONDITIONING

The possible origins of air conditioning smoke are:

- Air supply to the cabin:
  - From engines bleed (oil or hydraulic vapor), or truck exhaust sucked by the aircraft, or
  - From APU bleed (oil vapor), or
  - From external power which is prone to trigger false alerts on ground (contaminated air supply).

Continued on the following page

FIRE SMOKE/FUMES (Cont'd)

- Re-circulation fans, which propagate contaminated air in all the pressurized areas.

The entire airplane is fed with the smoke and many smoke detection may be triggered. They obviously do not appear simultaneously and are displayed in a completely erratic manner, one after each other and several minutes may separate each alert provided to the crew.
When identified, the only way to overcome the smoke generation is to switch off the affected bleed system.

SMOKE FROM CABIN EQUIPMENT

All enclosed cabin areas (crew rest, lavatories, ...) have dedicated smoke detectors and associated ECAM alerts.
Smoke from cabin equipment which is not automatically detected mainly concerns galleys, seats or IFE equipment. In that case , the alert comes from the cabin crew together with possible smells.
The cabin crew takes initial actions and reports to the cockpit crew.
Since GALLEYS are already switched off during immediate actions , the flight crew first sets the PAX SYS pb to OFF, this will shed IFE center, and the seat power supply.
If smoke continues, the flight crew sets COMMERCIAL 1+2 pb-sw to OFF, this will shed all aircraft commercial loads.

SMOKE FROM AVIONICS

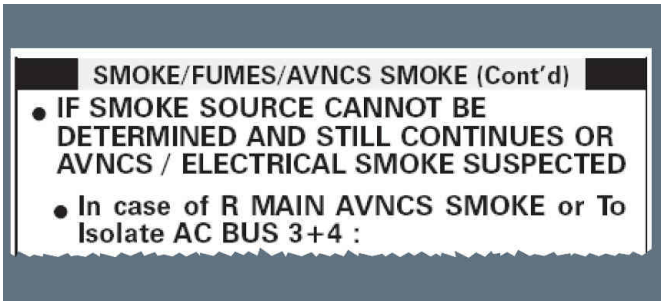
Each avionics bay has a smoke detection system, Main and Upper avionics are divided into Left and Right Main and Upper avionics with dedicated smoke detection system. For information on avionics smoke detection system, *Refer to DSC-26-50-10-10 Avionics Bays Smoke Detection* .

- SMOKE R MAIN AVNCS SMOKE
  In the case of SMOKE alert, the flight crew must apply the following part of the paper procedure:

Continued on the following page

FIRE SMOKE/FUMES (Cont'd)

Isolation of AC3 and AC4 busbars

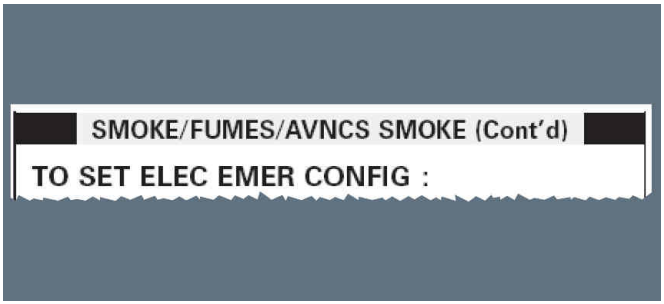


Right Main avionics equipment are mainly supplied by right electrical side (AC3, AC4 or DC2 busbars), therefore in the case of SMOKE R MAIN AVNCS SMOKE alert, AC3 and AC4 must be isolated and BUS TIE pb-sw set to OFF. This will shed AC3, AC4 and DC2 busbars.

However, some equipment in the Right Main avionics are supplied by the left electrical side (AC1, AC2 or DC1 busbars). If smoke continues following AC3, AC4 and DC2 shedding, AC1 and AC2 must be isolated. With BUS TIE pb-sw set to OFF, this will shed AC1, AC2 and DC1 busbars.

Finally smoke continuation may be an indication that affected equipment is supplied by both left electrical side (AC1, AC2, or DC1 busbars) and right electrical side (AC3, AC4, or DC2 busbars). The flight crew must set the emergency electrical configuration.

Emergency Electrical Configuration

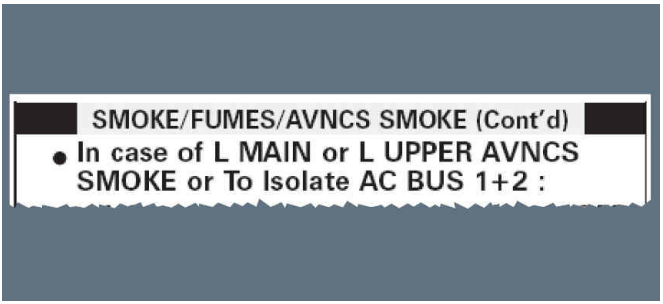


- SMOKE L MAIN AVNCS SMOKE
  Same situation as for Right Main avionics, however the flight crew begins to shed left electrical side (AC1, AC2, or DC1 busbars).

Continued on the following page

FIRE SMOKE/FUMES (Cont'd)

Isolation of AC1 and AC2 busbars



Then, if unsuccessful, the flight crew sheds the right electrical side (AC3, AC4 or DC2 busbars). Finally, if unsuccessful, they must set the emergency electrical configuration.

- SMOKE L UPPER AVNCS SMOKE
  Even if most of the equipment located in this bay are supplied by AC ESS busbar, some remain supplied by normal busbars.
  Therefore, the same procedures as for Left Main avionics must be applied.
- SMOKE R UPPER AVNCS SMOKE
  All equipments located in this bay are supplied by AC ESS busbar, therefore only immediate actions and diversion must be applied.

SMOKE SOURCE CANNOT BE DETERMINED

If the smoke source cannot be determined, the flight crew applies the same part of the paper procedure as for avionics smoke.
The flight crew must isolate AC3 and AC4 busbars and set BUS TIE pb-sw to OFF. This will shed AC3, AC4 and DC2 busbars.
Then, if unsuccessful, the flight crew must isolate AC1 and AC2 busbars and set BUS TIE pb-sw to OFF. This will shed AC1, AC2 and DC1 busbars.
Finally, if unsuccessful, set emergency electrical configuration.

Continued on the following page

•At ANY TIME of the procedure, if smoke/fumes becomes the GREATEST THREAT :
SMOKE FUMES REMOVAL..... CONSIDER

•At ANY TIME of the procedure, if situation becomes UNMANAGEABLE :
IMMEDIATE LANDING..... CONSIDER
Captain should consider an overweight landing, a tailwind landing, a ditching, a forced landing or a forced off-airport landing.

Continued on the following page

FIRE SMOKE/FUMES (Cont'd)

L2

Guidelines to determine smoke source :

- If smoke initially comes out of the cockpit's ventilation outlets, or if smoke is detected in the cabin, the crew may suspect an AIR COND SMOKE. In addition, very shortly thereafter, several SMOKE warnings (cargo, lavatory, avionics) will be triggered. The displayed ECAM procedures must therefore be applied,
- After an ENG or APU failure, smoke may come from the faulty item via the bleed system and be perceptible in the cockpit and/or cabin. In that case, it will be re-circulated throughout the aircraft, until it completely disappears from the air conditioning system.
- If only the AVIONICS SMOKE warning is triggered, the crew may suspect avionics smoke,
- If smoke is detected, while an equipment is declared faulty, the crew may suspect that smoke is coming from this equipment

Continued on the following page

  - **In case of R MAIN AVNCS SMOKE or To ISOLATE AC BUS 3+4 :**

L2

Right electrical side (AC3, AC4 or DC2 busbars) supplies most of the avionics equipment located in the Right Main avionics bay. Therefore in case of SMOKE R MAIN AVNCS SMOKE alert, the flight crew must shed first AC3, AC4 and DC2 busbars.

However, some equipment in the Right Main avionics are supplied by the left electrical side (AC1, AC2 or DC1 busbars). If smoke continues following AC3, AC4 and DC2 shedding, AC1 and AC2 must be isolated. With BUS TIE pb-sw set to OFF, this will shed AC1, AC2 and DC1 busbars.

Continued on the following page

FIRE SMOKE/FUMES (Cont'd)

Finally smoke continuation may be an indication that affected equipment is supplied by both left electrical side (AC1, AC2, or DC1 busbars) and right electrical side (AC3, AC4, or DC2 busbars). The flight crew must set the emergency electrical configuration.

LOSS OF BRAKING

Applicable to: ALL

This emergency procedure is not displayed on the ECAM , and should be performed by memory if the braking system does not automatically reconfigure after a significant failure.

- **If no braking :**

	REV.....MAX	PF
L2	*If needed, the flight crew may keep maximum reverse thrust until full aircraft stop.*	
L1	BRAKE PEDALS.....RELEASE	
L2	*When the flight crew sets the A-SKID to OFF, the control of the braking system is transferred from the BCS to the EBCU , and the emergency braking mode is activated. Consequently the CAPT should release the brake pedals before the F/O selects the A-SKID off. This action avoids brutal braking application.* *For information on the emergency braking mode, Refer to DSC-32-10-30-30-40 Emergency Braking .*	
L1	A-SKID.....ORDER	PF
L2	*The CAPT orders the F/O to select the A-SKID OFF.*	
L1	A-SKID.....OFF	PNF
	BRAKE PEDALS.....PRESS	PF
L2	*The pressure on the brakes is automatically limited.*	

L1 - **If still no braking :**

	PARK BRK.....ON	PF
L2	*The ultimate braking mode is activated. If the ground spoilers are not extended, the parking brake only is activated.* *For information on the ultimate braking mode, Refer to DSC-32-10-30-30-50 Ultimate Braking .* *For information on the parking brake, Refer to DSC-32-10-30-30-60 Parking Brake .*	

RUNWAY OVERRUN WARNING

Applicable to: ALL

ANNUNCIATIONS

Triggering Conditions:

L2 The Runway Overrun Warning (ROW) function detects that the aircraft is in position to overrun the runway.
These alerts are triggered between 500 ft RA and the start of braking or when the flight crew selects the reversers.

The function displaysone of the following message on the PFD:
- IF WET : RWY TOO SHORT
- RWY TOO SHORT

Associated to the RWY TOO SHORT message, an aural warning is triggered below 200 ft RA.
Indications:

Audio	SD page
Runway Too Short	

PFD

Continued on the following page

RUNWAY OVERRUN WARNING (Cont'd)

L2 The runway overrun warning is approved based on landing performance on dry or wet runway with no failure affecting landing distances.

L3 In the case of a failure that affects landing distance, unless ROW/ROP is declared inoperative, the runway overrun protection remains available. However ROW does not take into account the impact of the failure on the landing distance. Therefore, if the runway overrun warning activates during the final approach, the flight crew must apply the associated procedure.

L2 When the flight crew lands on a contaminated runway with an autobrake mode selected, the runway overrun warning remains active but does not prevent runway excursion in such conditions. Nevertheless, if the alerts are triggered during the approach on a contaminated runway, the flight crew must apply the associated procedure.

L1 ● **If IF WET : RWY TOO SHORT message is displayed on the PFD:**

- **If the runway is not dry :**

  GO-AROUND..... PERFORM

- **If the runway is dry :**

  CONTINUE

● **If RWY TOO SHORT message is displayed on the PFD with the associated aural warning:**

GO-AROUND.....PERFORM

RWY OVERRUN PROTECTION

Applicable to: ALL

ANNUNCIATIONS

Triggering Conditions:

L2 The Runway Overrun Protection (ROP) alert is triggered and protections activate when the ROP function detects a runway overrun situation.
The ROP alert may be triggered from the activation of the autobrake or when the flight crew selects the reversers, until the full stop of the aircraft.

Indications:

Audio
MAX REVERSE

SD page

PFD

Continued on the following page

RWY OVERRUN PROTECTION (Cont'd)

L2 The runway overrun protection is approved based on braking performance on dry and wet runway with no failure impacting the braking performance.
On contaminated runway, the runway overrun protection does not prevent runway overrun. Nevertheless the runway overrun protection remains armed. If the runway overrun protection activates, the flight must follow the associated procedure.
When the flight warning system triggers an alert that impacts the landing performance, the flight warning system declares ROP as inoperative system because ROP does not take into account the impact of the triggered alert on the landing distance. Nevertheless, the runway overrun protection remains armed. If the runway overrun protection activates during the rollout, the flight crew must apply the associated procedure.

Associated to the activation of this alert:
- The autobrake automatically applies maximum braking,
- The message MAX REVERSE is displayed on PFD
- The aural warning MAX REVERSE is continuously repeated as long as the flight crew does not select full reversers and ROP is active
- The stop bar turns to red pulsing on OANS as long as it remains beyond the end of the runway. The braking distance indication turns to red
- At 80 kt, if the ROP is still active while reversers are selected at MAX, the aural warning KEEP MAX REVERSE is triggered one time.

L1	MAX REVERSE.....SELECT/KEEP	PF

Intentionally left blank

UNRELIABLE AIR SPEED INDICATION - ABOVE FL 250 - ALERT

Applicable to: ALL

Impacted DU: NONE

● **If the safe conduct of the flight is impacted:**

MEMORY ITEMS:

AP	DISCONNECT
A/THR	DISCONNECT
FD	DISCONNECT
PITCH/THRUST	5°/CLB
SPEED BRAKES	Check retracted
Level off for troubleshooting	

RISK OF UNDUE OVERSPEED WARNING

L2 *The overspeed warning is not inhibited, if the flight control computers reject the ADRs.*

L1 ● **To level off for troubleshooting:**

AP..... DISCONNECT
A/THR..... DISCONNECT
FD..... DISCONNECT

PITCH (°) / THRUST (% THR) FOR LEVEL FLIGHT

		550 t	450 t	350 t
FL	**Speed**	**Pitch (°) / Thrust (% THR)**		
FL 250-FL 290	300 kt	2.5 / 68	2 / 58	1.5 / 48
FL 300-FL 330		2.5 / 78	2 / 68	1.5 / 58
FL 340-FL 370	M 0.85	2.5 / 88	2 / 78	1.5 / 68
Above FL 370		-	2 / 88	1.5 / 78

CAUTION	If the failure is due to radome destruction, the drag will increase and therefore THR must be increased by 5%. The fuel consumption will increase by about 10%.

AIR DATA (ADRs/STBY INSTR)..... XCHECK

L2 *Crosscheck all speeds and altitudes indications.*

Alternate sources may be used to evaluate the air data:
- *GPS altitude*
- *GPS and IRS Ground Speeds, taking into account altitude and wind effect.*

Continued on the following page

UNRELIABLE AIR SPEED INDICATION - ABOVE FL 250 - ALERT (Cont'd)

L1 ■ **If at least one air data is reliable:**

RELIABLE AIR DATA..... USE

AT LEAST ONE ADR : KEEP ON

L2 *Maintain at least one ADR to ON, in order to prevent the display of the backup scales (i.e. BUSS and GPS altitude) in the case of the three ADRs failure with ISIS reliable because the ISIS data are more accurate than the backup scales data.*

L1 UNRELIABLE ADRs P/Bs..... OFF

L2 *Set unreliable ADRs to OFF, in order to prevent the fight controls operation with erroneous air data sources.*
In the case of the three ADRs failure with the ISIS reliable, the flight crew must switch off only two ADRs.

L1 ECAM ACTIONS..... PERFORM

L2 *Return to the ECAM to complete the ECAM actions (i.e. Perform the actions of the abnormal alert displayed following the ADRs switching off).*

L1 ■ **If no air data is reliable:**

ONE ADR: KEEP ON

L2 Maintain one ADR to ON, in order to prevent the display of the backup scales (i.e. BUSS and GPS altitude) on the PFD.

L1 TWO ADRs P/Bs..... OFF

L2 *Set two ADRs to OFF, in order to avoid flying normal law with erroneous air data parameters coming from ADRs.*

L3 *When the flight controls use the air data parameters coming from one ADR, there is a reversion to Alternate 2 or direct law accordingly to the remaining erroneous air data (i.e. the remaining ADR to ON and the ISIS).*

L1 ● **At Top of Descent**

Set the thrust to IDLE

FL	Pitch(°) / Thrust (%THR)
Above FL 330	-0.5 / IDLE
FL 330-FL 250	0 / IDLE

● **When below FL 250, if air data still unreliable:**

ADRs 1+2+3 P/Bs..... OFF

Note: The NAV ADR 1+2+3 FAULT alert will trigger. Complete QRH actions before performing ECAM actions.

Continued on the following page

UNRELIABLE AIR SPEED INDICATION - ABOVE FL 250 - ALERT (Cont'd)

L2 *Set all ADRs to OFF, in order to replace the PFD's normal speed scale and altitude indication by the backup scales (i.e. BUSS and GPS altitude).*

L1 SPEED.....FLY THE GREEN

L2 *Fly within the green area of the speed scale to ensure safe flight.*
For slats/flaps retraction, it is better to fly at the top of the green area of the speed scale.
Before extending the slats/flaps, it is better to fly at the bottom of the speed scale green area, and to be in straight flight.

L1 CABIN ALT MODE..... MAN
CABIN ALT TRGT.....LDG ELEVN

SPD BRK : DO NOT USE

L2 *The BUSS is tuned for the aerodynamic model with the speed brake retracted. The flight crew must not extend the speed brake because it would affect the relation between Angle of Attack and airspeed, therefore making the BUSS unreliable.*

L1 FOR NAV : USE STBY INSTRUMENTS

FMS F-PLN & PRED NOT AVAILABLE

AVOID ICING CONDs
ECAM ACTIONS.....PERFORM

L2 *Return to the ECAM to complete the ECAM actions (i.e. Perform the actions of the NAV ADR 1+2+3 FAULT alert)*

Intentionally left blank

SURV GLIDE SLOPE, GLIDE SLOPE ALERT

Applicable to: ALL

ANNUNCIATIONS

Triggering Conditions:

L2 The TAWS (in the SURV system) detects when the aircraft descends below the glide slope by more than 1.3 dots, during an ILS approach.

Indications:

Audio

CAUTION	During night or IMC conditions, apply the procedure immediately. Do not delay reaction for analysis. During daylight VMC conditions, with terrain and obstacles clearly in sight, the alert may be considered to be a caution. Take positive corrective action until the alert ceases, or until a safe trajectory is ensured.

Stabilize the aircraft on the glide slope.

- **If flight crew intentionally flies below the glide slope (i.e. a Non-Precision Approach):**

  G/S MODE.....OFF

L2 *The flight crew turns off the G/S MODE button on:*
- *The SURV/CONTROLS page of the MFD, or*
- *The SURV panel.*

SURV GO AROUND, WINDSHEAR AHEAD

Applicable to: ALL

ANNUNCIATIONS

Triggering Conditions:

L2 The Predictive Windshear System (in the SURV system) detects windshear (predictive windshear) during the approach phase.

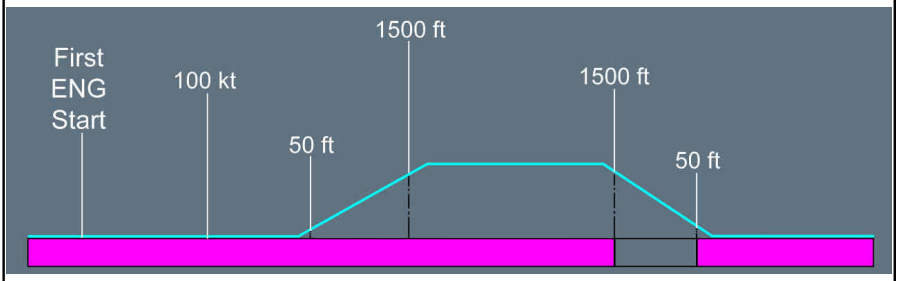
Indications:

Audio

SD page

PFD

Flight Phase Inhibition:



Continued on the following page

SURV GO AROUND, WINDSHEAR AHEAD (Cont'd)

Apply the following procedure at landing, if the PWS triggers:
- The W/S AHEAD warning on the PFDs
- The associated GO AROUND, WINDSHEAR AHEAD aural alert
- The location of windshear on the ND.

● **At landing:**

L2 *Note: If the flight crew verifies and confirms that there is no risk of windshear, they may disregard the alert, provided that:*
- *There are no other signs of possible windshear conditions*
- *The reactive windshear function is operative.*

There are reported cases that specific environments (e.g. obstacles) cause the spurious triggering of predictive windshear alerts, during either takeoff or landing. However, the flight crew must always rely on all reactive windshear (i.e. WINDSHEAR) alerts.

L1 GO AROUND.....PERFORM

L2 *It is permitted to change the slats/flaps configuration, provided that the aircraft does not enter a windshear.*

L1 L/G UP.....SELECT

SRS ORDERS.....FOLLOW

L2 *If necessary, the flight crew may apply full backstick.*

Note:
- *If the autopilot is engaged, it will disengage, when the angle-of-attack goes above alpha prot.*
- *If the FD is not available, select an initial pitch attitude of 12.5 °. Then, if necessary, increase the pitch attitude, in order to minimize the decrease in altitude.*

SURV MONITOR RADAR DISPLAY

Applicable to: ALL

ANNUNCIATIONS

Triggering Conditions:

L2 The Predictive Windshear System (in the SURV system) detects windshear (predictive windshear) during the approach phase.

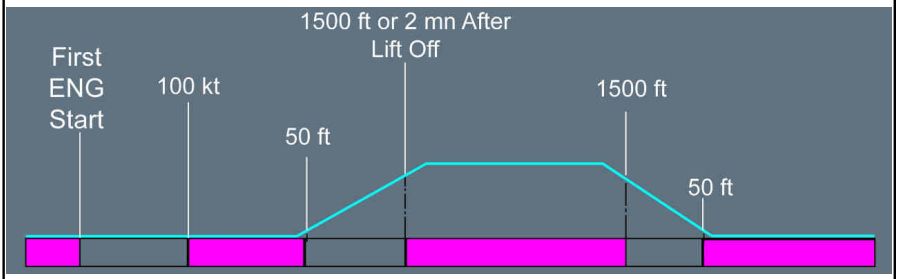
Indications:

Audio

SD page

PFD

Flight Phase Inhibition:



Apply the precautionary steps, as indicated in the SUSPECTED WINDSHEAR procedure (*Refer to procedure*), if the PWS triggers:

- The W/S AHEAD caution on the PFD s
- The associated MONITOR RADAR DISPLAY aural alert
- The location of windshear on the ND .

SURV PULL UP ALERTS

Applicable to: ALL

ANNUNCIATIONS

Triggering Conditions:

L2 The TAWS (in the SURV system) detects:
- An excessive rate of descent at low altitude (PULL UP alert), or
- A terrain collision threat ahead of the aircraft (TERRAIN AHEAD, PULL UP alert), or
- An obstacle collision threat ahead of the aircraft (OBSTACLE AHEAD, PULL UP alert).

For more information on the aural alerts, *Refer to DSC-34-20-20-20 Aural Alerts* .

Indications:

SD page

PFD

Continued on the following page

SURV PULL UP ALERTS (Cont'd)

CAUTION	During night or IMC conditions, apply the procedure immediately. Do not delay reaction for analysis. During daylight VMC conditions, with terrain and obstacles clearly in sight, the alert may be considered to be a caution. Take positive corrective action until the alert ceases, or until a safe trajectory is ensured.

- **If the TAWS triggers one of the PULL UP alerts, apply the following procedure:**

AP.....DISENGAGE
PITCH.....PULL UP

Pull up to full backstick and maintain in that position.

THRUST LEVERS.....TOGA
SPEED BRAKE LEVER.....CHECK RETRACTED
BANK.....WINGS LEVEL or ADJUST

L2 *Aircraft achieve the best climb performance when the wings are as level as possible. If the "TERRAIN AHEAD, PULL UP" alert or the "OBSTACLE AHEAD, PULL UP" alert is triggered, the flight crew can initiate a turning maneuver while climbing, provided that turning is the safest action.*

L1 - **If the flight path is safe, and the GPWS warning stops:**

PITCH.....REDUCE
SPEED.....ACCELERATE

- **If the speed is above VLS, and the vertical speed is positive:**

FLAPS ZERO.....AS RQRD

SURV RESOLUTION ADVISORY ALERTS

Applicable to: ALL

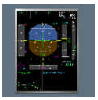
ANNUNCIATIONS

Triggering Conditions:

L2 The TCAS (in the SURV system) detects a Resolution Advisory (RA).
For more information on the aural alerts, *Refer to DSC-34-20-40-20 Aural Alerts* .

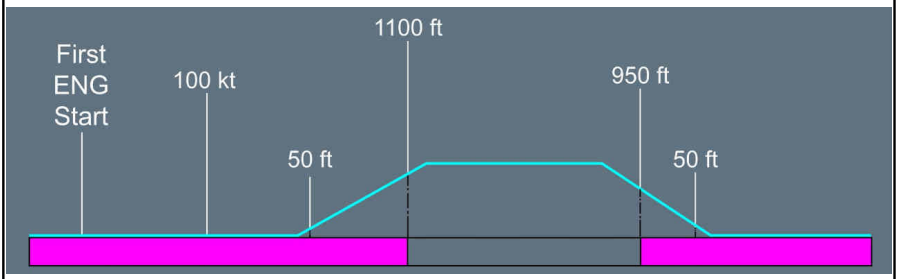
Indications:

SD page



PFD

Flight Phase Inhibition:



Continued on the following page

SURV RESOLUTION ADVISORY ALERTS (Cont'd)

L2 There are two types of Resolution Advisories (RA):

- Preventive RA s
  A preventive RA is announced by the "MONITOR VERTICAL SPEED" aural alert. For more information on the aural alerts, *Refer to 34 / SURV / TCAS / Controls and Indicators / Aural Alerts* .
- Corrective RA s.

  A corrective RA is announced by one of the following aural alerts:
  - "CLIMB, CLIMB"
  - "CLIMB, CROSSING CLIMB, CLIMB, CROSSING CLIMB"
  - "CLIMB, CLIMB NOW, CLIMB, CLIMB NOW"
  - "INCREASE CLIMB, INCREASE CLIMB"
  - "DESCEND, DESCEND"
  - "DESCEND, CROSSING DESCEND, DESCEND, CROSSING DESCEND"
  - "INCREASE DESCENT, INCREASE DESCENT"
  - "DESCEND, DESCEND NOW, DESCEND, DESCEND NOW"
  - "MAINTAIN VERTICAL SPEED, MAINTAIN"
  - "MAINTAIN VERTICAL SPEED, CROSSING MAINTAIN"
  - "ADJUST VERTICAL SPEED, ADJUST".

  For more information on the aural alerts, *Refer to 34 / SURV / TCAS / Controls and Indicators / Aural Alerts* .

If the AP / FD TCAS mode is available, the AP / FD TCAS mode engages. For more information on the AP / FD TCAS mode availability, *Refer to DSC-22-FG-70-110-10 AP/FD TCAS Mode Availability* .
When the AP / FD TCAS mode engages, the flight crew must apply the AP / FD TCAS procedure: *Refer to AP/FD TCAS Procedure* .
If the AP / FD TCAS mode does not engage, the flight crew must apply the basic TCAS procedure: *Refer to Basic TCAS Procedure* .

Continued on the following page

SURV RESOLUTION ADVISORY ALERTS (Cont'd)

AP / FD TCAS PROCEDURE

L2 The flight crew applies this procedure, when a Resolution Advisory (RA) is triggered, and the AP / FD TCAS mode engages. The AP / FD TCAS mode follows the RA orders.
For more information on the AP / FD TCAS mode engagement following a RA , *Refer to DSC-22-FG-70-110-40-GNRA Introduction* .

L1 Always follow the RA orders, even if this results in crossing the intruders altitude, because these orders ensure the best altitude separation.

CAUTION	Be aware that the intruder may have a TCAS , and may maneuver in response to a coordinated RA order. Therefore, not following an RA order could compromise safe separation.

- **If the PF uses the Head-Up Display (HUD):**

Revert to PFD .

L2 *The HUD does not display the green and red areas of the vertical speed scale.*

L1 - **If the AP is off:**

FD ORDERS ..... FOLLOW

The AP can be engaged.

VERTICAL SPEED..... MONITOR

L2 *If a preventive RA was triggered: Check that the vertical speed remains out of the red area of the vertical speed scale.*
If a corrective RA was triggered: Check that the vertical speed gets out of the red area, and remains in the green area of the vertical speed scale.

L1

CAUTION	*If for any reason during an RA , the aircraft vertical speed does not reach the green area of the vertical speed scale. the Pilot Flying (PF) should disconnect the AP , and override the FD orders, in order to lead the aircraft vertical speed out of the red area of the vertical speed scale.* *If necessary, the PF must use the full speed range between* $V\alpha_{max}$ *and VMAX .*

- **If any "CLIMB" aural alert sounds during the final approach:**

AP / FD TCAS ORDERS .....
..... MONITOR/FOLLOW
GO-AROUND..... CONSIDER

Continued on the following page

SURV RESOLUTION ADVISORY ALERTS (Cont'd)

L2 *If the flight crew performs a go-around, the AP / FD TCAS mode disengages, and the SRS GA mode engages. The AP / FD does no longer follow the RA orders. The flight crew must follow the vertical speed indications on the vertical speed scale. The flight crew must then apply the basic TCAS procedure: Refer to PRO-ABN-NECA-34-20-570 TCAS Procedure .*

L1 Respect stall, GPWS , or windshear warning.
ATC..... NOTIFY

- **When "CLEAR OF CONFLICT" aural alert sounds:**

L2 The AP / FD TCAS mode disengages. For more information, *Refer to DSC-22-FG-70-110-40-GNCOC Introduction .*

L1 AP / FD .....MONITOR/FOLLOW
ATC.....NOTIFY
LATERAL AND VERTICAL GUIDANCE..... ADJUST

L2 *The flight crew should engage an appropriate vertical mode, or adjust the vertical speed target, in accordance with the latest ATC clearance.*

L1 SPEED.....ADJUST

L2 *The flight crew should adjust the speed target, and revert to managed speed, as appropriate.*

Continued on the following page

SURV RESOLUTION ADVISORY ALERTS (Cont'd)

BASIC TCAS PROCEDURE

The flight crew must apply the basic TCAS procedure, if a corrective RA is triggered, and the AP/FD TCAS does not engage.

- **If the PF uses the Head-Up Display (HUD):**

Revert to PFD.

L2 *The HUD does not display the green and red areas of the vertical speed scale.*

L1 Always follow RA orders, even if this results in crossing the intruders altitude, because these orders ensure the best altitude separation.

CAUTION	Be aware that the intruder may have a TCAS, and may maneuver in response to a coordinated RA order. Therefore, not following an RA order could compromise safe separation.

AP (if engaged)..... OFF
FDs..... OFF
Respond promptly and smoothly.
VERTICAL SPEED..... ADJUST or MAINTAIN

L2 *Adjust or maintain vertical speed as required, depending on the green area, and/or to avoid the red area of the vertical speed scale.*

Note: Avoid excessive maneuvers while attempting to maintain the vertical speed just outside the red area of the scale, and within the green area. If necessary, use the full speed range between $V\alpha_{max}$ and V_{max}.

L1 Respect stall, GPWS, or windshear warnings.
ATC..... NOTIFY

- **When the "CLEAR OF CONFLICT" aural alert sounds:**

ATC..... NOTIFY
LATERAL AND VERTICAL GUIDANCE..... ADJUST

L2 *Adjust the lateral and vertical guidance to resume normal navigation, in accordance with ATC clearance.*

L1 AP/FD..... AS RQRD

L2 *If necessary, reengage the AP/FD.*

Continued on the following page

SURV RESOLUTION ADVISORY ALERTS (Cont'd)

L1 ● **If any "CLIMB" aural alert sounds during the final approach:**

GO-AROUND.....PERFORM

SURV SINK RATE, SINK RATE - DON'T SINK, DON'T SINK ALERTS

Applicable to: ALL

ANNUNCIATIONS

Triggering Conditions:

L2 The TAWS (in the SURV system) detects:
- A high rate of descent at low altitude (SINK RATE, SINK RATE alert), or
- A rate of descent during the initial climb after takeoff, or during a go-around (DON'T SINK, DON'T SINK alert).

For more information on the aural alerts, *Refer to DSC-34-20-20-20 Aural Alerts* .

Indications:

SD page

PFD

CAUTION	During night or IMC conditions, apply the procedure immediately. Do not delay reaction for analysis. During daylight VMC conditions, with terrain and obstacles clearly in sight, the alert may be considered to be a caution. Take positive corrective action until the alert ceases, or until a safe trajectory is ensured.

Take positive corrective action until the alert ceases, or until a safe trajectory is ensured.

GO-AROUND procedure.....PERFORM

SURV TRAFFIC ADVISORY ALERT

Applicable to: ALL

ANNUNCIATIONS

Triggering Conditions:

L2 The TCAS (in the SURV system) detects a Traffic Advisory (TA).

Indications:

Audio

L2 If the AP / FD TCAS mode is available, the AP / FD TCAS mode arms. For more information, *Refer to DSC-22-FG-70-110-40-GNTA Introduction* .

L1 TCAS mode ..... CHECK ARMED (blue)

L2 *When the AP / FD TCAS mode arms, the flight crew must be prepared to apply the AP / FD TCAS procedure in the case of a Resolution Advisory.*
If the AP / FD TCAS mode does not arm, the flight crew must be prepared to apply the basic TCAS procedure in the case of a Resolution Advisory.

L1 ● **If the A/THR is off:**

A/THR ..... ON

L2 *The flight crew should set the A/THR ON to avoid the triggering of the AUTO FLT A/THR LIMITED alert at the A/THR activation, in the case of a Resolution Advisory.*

L1 Do not perform a maneuver based on a TA alone.

SURV WINDSHEAR AHEAD, WINDSHEAR AHEAD

Applicable to: ALL

ANNUNCIATIONS

Triggering Conditions:

L2 The Predictive Windshear System (in the SURV system) detects windshear (predictive windshear) during the takeoff phase.

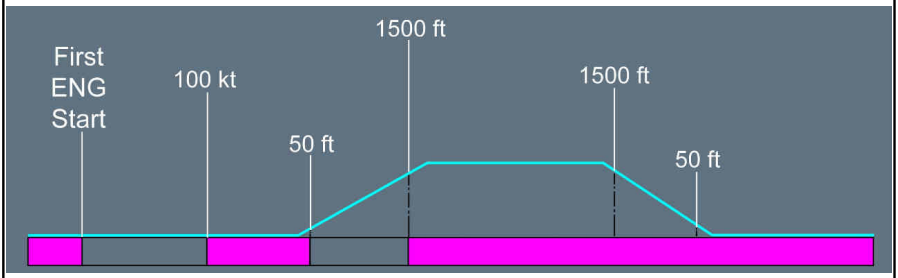
Indications:

Audio

SD page

PFD

Flight Phase Inhibition:



Continued on the following page

SURV WINDSHEAR AHEAD, WINDSHEAR AHEAD (Cont'd)

Apply the following procedure on ground, before and during takeoff, if the PWS triggers:
- The W/S AHEAD warning on the PFDs
- The associated WINDSHEAR AHEAD, WINDSHEAR AHEAD aural alert
- The location of windshear on the ND.

■ On ground:

L2 Note: *If the flight crew verifies and confirms that there is no risk of windshear, they may disregard the alert, provided that:*
- *There are no other signs of possible windshear conditions*
- *The reactive windshear function is operative.*

There are reported cases that specific environments (e.g. obstacles) cause the spurious triggering of predictive windshear alerts, during either takeoff or landing. However, the flight crew must always rely on all reactive windshear (i.e. WINDSHEAR) alerts.

L1 ■ **Before takeoff:**

TAKEOFF..... DELAY

L2 *Delay takeoff, until weather conditions improve.*

L1 MOST SUITABLE RUNWAY..... SELECT

L2 *When selecting the most suitable runway, take into account the location of predicted windshear.*

L1 ■ **During the takeoff run:**

TAKEOFF..... REJECT

L2 *Predictive windshear alerts are inhibited above 100 kt, and until the aircraft reaches 50 ft.*

L1 ■ **When airborne, at initial climb:**

THR LEVERS..... TOGA

L2 It is permitted to change the slats/flaps configuration, provided that the aircraft does not enter a windshear.

L1 SRS ORDERS..... FOLLOW

L2 Note: *If the autopilot is engaged, it will disengage, when the angle-of-attack goes above alpha prot.*

SURV WINDSHEAR, WINDSHEAR, WINDSHEAR

Applicable to: ALL

ANNUNCIATIONS

Triggering Conditions:

L2 The PRIMs detect windshear (reactive windshear).

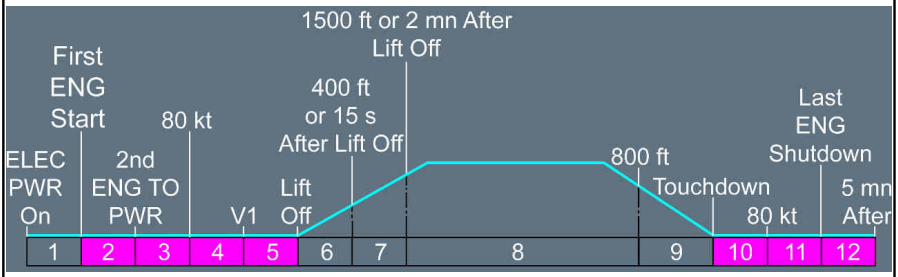
Indications:

Audio

SD page

PFD

Flight Phase Inhibition:



Both PFDs display the WINDSHEAR warning, during the takeoff and landing phases. This warning is associated with a WINDSHEAR, WINDSHEAR, WINDSHEAR aural alert.

Continued on the following page

SURV WINDSHEAR, WINDSHEAR, WINDSHEAR (Cont'd)

If windshear is detected, either by the systems, or by the flight crew, apply the following recovery techniques:

■ **On ground, at takeoff:**

L2 During the takeoff roll, WINDSHEAR, WINDSHEAR, WINDSHEAR alert is inhibited. Windshear recognition is based on the flight crew observation.

L1 ● **Before V1:**

If there are significant variations in airspeed, and in airspeed trend below the indicated V1, reject the takeoff.

L2 *If windshear occurs during the takeoff roll, the aircraft may reach V1 later (or sooner) than expected. The flight crew should ensure that there is sufficient runway remaining to stop the aircraft, if necessary.*

L1 ● **After V1:**

THR LEVERS.....TOGA
REACHING VR.....ROTATE NORMALLY
SRS ORDERS..... FOLLOW

■ **When airborne, during initial climb, or at landing:**

THR LEVERS AT TOGA..... SET OR CONFIRM
AP (if engaged).....KEEP ENGAGED
SRS ORDERS.....FOLLOW

L2 *If necessary, the flight crew may apply full backstick.*

Note: - *If the autopilot is engaged, it will disengage, when the angle-of-attack goes above alpha prot.*
- *If the FD is not available, select an initial pitch attitude of 12.5 ° . Then, if necessary, increase the pitch attitude, in order to minimize the decrease in altitude.*

L1 DO NOT CHANGE CONFIGURATION (SLATS/FLAPS, GEAR) UNTIL OUT OF WINDSHEAR.

CAREFULLY MONITOR FLIGHT PATH AND SPEED.

RECOVER SMOOTHLY TO CLIMB, WHEN OUT OF WINDSHEAR.

SMOKE/FIRE PROCEDURE

Applicable to: ALL

L2 If smoke is detected in the Flight Crew Rest Compartment (FCRC):
- A single low chime sounds for 30 s
  After the single low chime, a repetitive triple chime sounds every 30 s.
- The smoke location message comes on and the red indicator light flashes on the Attendant Indication Panel (AIP)
- The FCRC lighting comes on at 100 % intensity.
- In the cockpit, the SMOKE FLT REST SMOKE alert is triggered.

L1 COMMUNICATION WITH THE FLIGHT CREW IN THE COCKPIT..... MAINTAIN
Search for smoke and fire in the FCRC.

L2 *Look at the bunks, closets, and stowage compartments.*

L1 ● **If there is no smoke or fire in the FCRC:**
SMOKE RESET pb ..... PRESS

L2 *By pressing the SMOKE RESET pb on the FAP or on the Additional Attendant Panel (AAP), it:*
- *Stops the chimes in the cabin*
- *Removes the visual alerts on the respective Area Call Panels (ACP) and AIPs.*

Note: The smoke indicator and the SMOKE RESET pb on the FAP smoke page remain displayed until the smoke has dissipated.

L1 ● **If there is smoke or fire in the FCRC:**
BASIC FIRE-FIGHTING PROCEDURE..... APPLY

L2 *Take the nearest appropriate fire extinguisher.*
Consider the use of a Protective Breathing Equipment (PBE).

L1 DEDICATED CREWMEMBER.....
..... MONITOR FCRC FOR THE REMAINDER OF THE FLIGHT

DEPRESSURIZATION

Applicable to: ALL

L2 If a depressurization occurs:

- A continuous high chime sounds
- The oxygen masks automatically drop down from the oxygen container, when the cabin altitude is more than 14 000 ft.

L1 OXYGEN MASKS..... ON
SEAT BELT..... FASTEN
CREW REST OCCUPANTS.....STAY INSIDE

L2 *Stay inside until the aircraft reaches a safe flight level.*

LATERAL ASYMMETRY MONITORING

Applicable to: ALL

Like all other aircraft, the A380 may have a small lateral asymmetry in flight.
In cruise, when the autopilot is engaged, the flight control laws compensate this possible lateral asymmetry via rudder and aileron deflection, while optimizing fuel burn and ensuring passenger comfort.

The autopilot achieves this optimized compensation by:
- Setting a small sideslip and bank angle up to a comfort limit

  Note: *The effect on drag of a small sideslip and bank angle is lower than the effect on drag that the rudder and aileron deflection would have if the autopilot targeted zero sideslip and zero bank angle.*

- The use of ailerons to keep the roll at the comfort limit.

Therefore, in cruise, the flight crew may observe a small sideslip, bank angle, and aileron deflection due to the compensation of a lateral asymmetry.

Note: *At high latitudes, even if perfectly symmetric, the aircraft may have an additional bank angle of ± 0.2 ° , due to the Coriolis acceleration. If the aircraft has a small lateral asymmetry in flight, the Coriolis effect partially compensates or amplifies the bank angle.*

The flight crew can use the following guidelines in order to define whether an observed asymmetry is excessive or not. Based on this monitoring and if appropriate, the flight crew should report the lateral asymmetry in the logbook.

FLIGHT CONDITIONS

In order to have a reliable asymmetry monitoring, the aircraft should be in the following conditions:
- There is no turbulence
- The aircraft flies straight and level at the cruise Mach (not higher than M 0.86) and close to the optimum flight level
- The autopilot is engaged and the lateral guidance mode is NAV
- The engine thrust is symmetrical

- The ECAM did not trigger any alert associated with the fuel system
- On the FUEL SD page:
  - There are no amber-underlined fuel quantities, and
  - The fuel imbalance in the wing tanks is not greater than:
    - 1 t between a feed tank and its opposite feed tank
    - 1.4 t between both inner tanks
    - 1.4 t between both mid tanks
    - 0.2 t between both outer tanks.

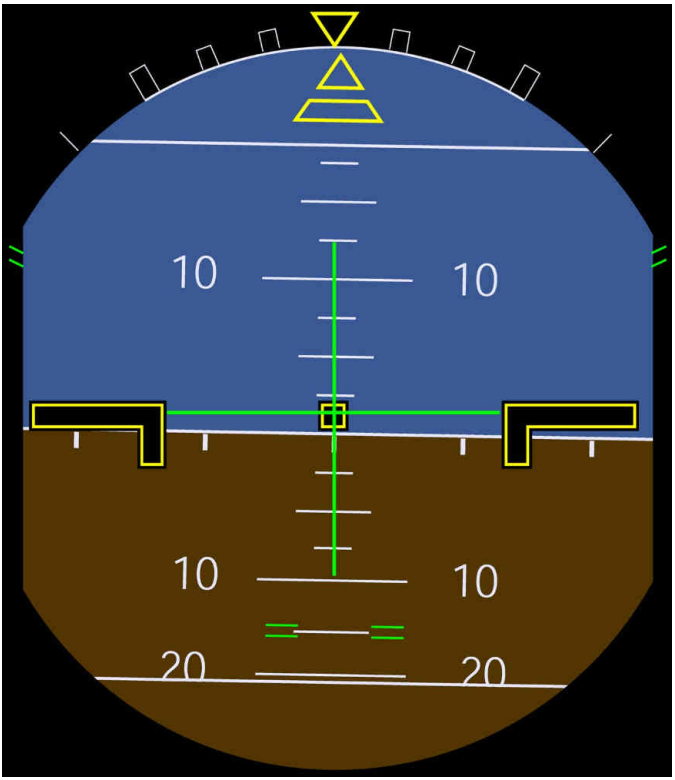
Note: *If the fuel imbalance is greater for at least one pair of tanks, the monitoring is not reliable. In this case, it is recommended to perform the monitoring later during the flight, when the fuel is better balanced.*

If the aircraft is in the above-listed conditions, the flight crew checks the bank angle on the PFD , and the aileron deflection on the F/CTL SD page:

BANK ANGLE ON PFD

Normal operations of the aircraft in stable horizontal flight may lead to a stabilized (left or right) bank angle of 0.7 ° , as illustrated below:

Bank Angle on PFD



If the stabilized bank angle (left or right) is higher than the bank angle on the illustration (0.7 °), the flight crew should:

- Press the ACMS TRIGGER pb , on the center pedestal

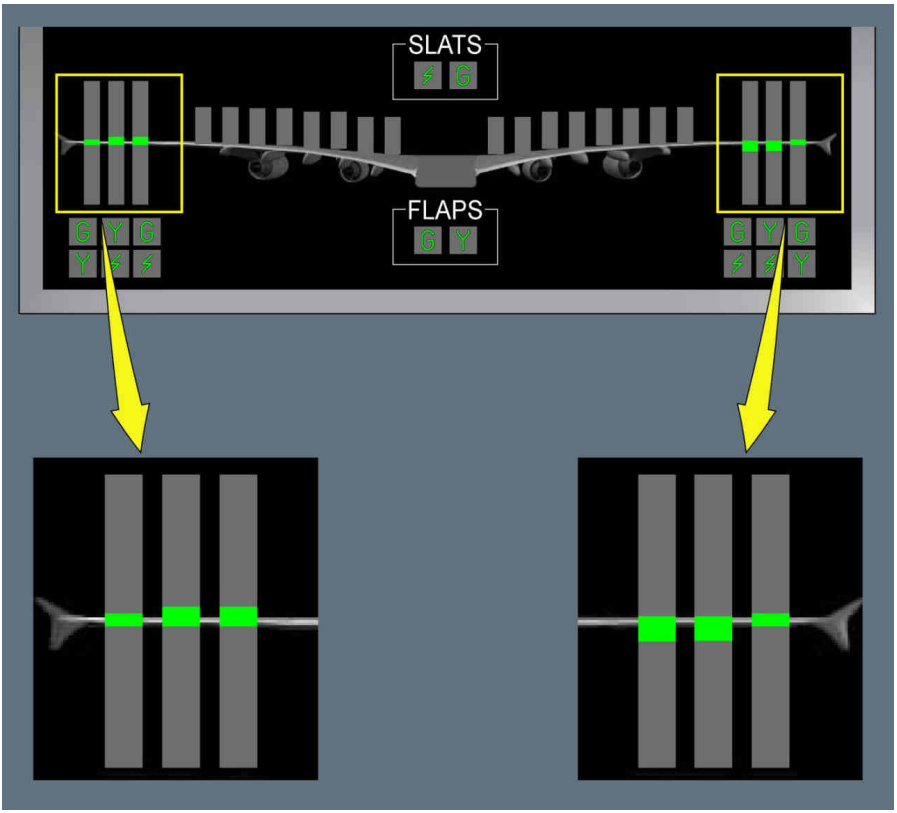
  Note: *The flight crew can disregard the reports that are automatically printed.*

  For more information, *Refer to ACMS TRIGGER pb* .
- Report the event in the logbook.

AILERON DEFLECTION ON THE F/CTL SD PAGE

Normal operations of the aircraft in stable horizontal flight may lead to a stabilized aileron deflection, as illustrated below:

Aileron Deflection on F/CTL SD Page



If the stabilized aileron deflection on the F/CTL SD page exceeds the deflection that is indicated on the illustration here above, the flight crew should:

- Press the ACMS TRIGGER pb , on the center pedestal

  Note: *The flight crew can disregard the reports that are automatically printed.*

  For more information, *Refer to ACMS TRIGGER pb*
- Report the event in the logbook.

REFUEL WITH ONE ENGINE RUNNING

Applicable to: ALL

Refuel with one engine running should only be performed when there is no available external power unit, and when the APU is inoperative.
If only one engine is running, the electrical power does not supply some of the transfer pumps. Therefore the automatic ground transfer is not available, and if necessary, the flight crew should apply the manual transfer when the refuel is completed.

Use the left-hand side fuel coupling that is opposite of the running engine.
ALL PASSENGERS.....DISEMBARK
AIRPORT AUTHORIZATION..... OBTAIN
The airport fire protection services should be near the aircraft during the entire refueling procedure.
Consider positioning the aircraft downwind, and at a location where the ground slope is negligible.
PARK BRK..... ON
Check the park brake pressure on the BRK PRESSURE indications.
ENG 3.....GROUND IDLE
L2 *Engine 3 enables the electrical supply of more avionics equipments and to pressurize the parking brake.*
L1 GEN 3 CONNECTED.....CHECK
Place the fuel truck under the extremity of the left wing.
The fuel truck pressure should not exceed 50 PSI.

If the refuel operations are in progress:
- Do not start engines 1, 4, 2
- Do not shut down engine 3.

AUTOMATIC or MANUAL REFUEL PROCEDURE.....APPLY
The refuel system must be fully operative.

OPERATIONS MONITORING DURING THE ENTIRE REFUEL PROCEDURE

FUEL TRUCK SHUTOFF VALVE.....MONITOR
Ensure that the fueling company controls permanently the emergency fuel shutoff devices.
One flight crewmember must be in the cockpit to monitor the systems and the running engine.
One qualified ground crewmember must be near the REFUEL panel to operate the controls switches, if the refuel is performed from the REFUEL panel. If the refuel is performed from the cockpit, the flight crew sets to ON the REFUEL pb-sw on the overhead panel to activate the refuel operations.

Intentionally left blank

DEFINITION OF ICING CONDITIONS

Applicable to: ALL

Icing conditions exist when OAT on the ground and for takeoff, or TAT in flight is 10 °C or below and visible moisture in any form is present (such as clouds, fog with visibility of one nautical mile or less, rain, snow, sleet or ice crystals).

Note: Ice crystals can be encountered near convective weather.

Icing conditions also exist when the OAT on the ground and for takeoff is 10 °C or below when operating on ramps, taxiways, or runways where surface snow, ice, standing water or slush may be ingested by the engines or freeze on engines, nacelles or engine sensor probes.

OPERATIONS IN ICING CONDITIONS

Applicable to: ALL

FLIGHT IN ICING CONDITIONS

ENGINE ANTI-ICE

Engine anti-ice must be ON during all ground and flight operations, when icing conditions exist or are anticipated, except during climb and cruise when the SAT is below –40 °C .
Engine anti-ice must be ON before and during a descent in icing conditions, even if the SAT is below –40 °C .

WING ANTI-ICE

The flight crew may use wing anti-ice either to prevent the ice accretion, or to remove an ice accumulation from the wing leading edge.
The flight crew should turn wing anti-ice ON whenever there is an indication that the airframe is icing up. The indication may be an accumulation of ice on the visual ice indicator (between the cockpit windshields), or when the A-ICE SEVERE ICE DETECTED caution triggers.

CAUTION	1. The flight crew should avoid extended flight in icing conditions with the slats extended. 2. If there is evidence of significant ice accretion and to take into account ice formation on non heated structure, the minimum speed should be: - Green Dot in clean configuration - VLS in CONF 1, 2, 3 and FULL 3. If there is evidence of ice accretion on de-iced parts of the airframe (WING ANTI ICE inoperative (*Refer to PRO-ABN-ECAM-10-30-110 A-ICE L(R) WING VLV CLOSED* , *Refer to PRO-ABN-ECAM-10-30-100 A-ICE L(R) WING VLV PRESS LO*)), the minimum speed should be: - Green Dot in clean configuration - VLS in CONF 1, 2, and 3 (Landing configuration is CONF 3)

GROUND OPERATIONS IN ICING CONDITIONS

- For ground operations on contaminated runways: *Refer to Fluid Contaminated Runways*
- For aircraft preparation and/or securing the aircraft in cold weather: *Refer to Cold Weather Procedures*
- For engine operations on ground: *Refer to Standard Operating Procedures*

THRUST APPLICATION ON BRAKES

Applicable to: ALL

The braking system is not designed to hold the aircraft in a stationary position when a high thrust level is applied on at least one engine.

The thrust level from which the aircraft starts to move (with parking brake set to ON or with manual braking applied) depends on several factors such as:

- Ground surface conditions
- Environment
- The aircraft weight
- Etc ...

During ground procedures that require a thrust increase with braking, the flight crew must ensure that the aircraft remains stationary, and one flight crew must keep his/her hands on the thrust levers to be ready to immediately retard the thrust levers to IDLE if the aircraft starts to move.

Intentionally left blank

TAWS

Applicable to: ALL

During cockpit preparation, the flight crew must set all TAWS settings to ON, by selecting DEFAULT SETTINGS on the SURV/CONTROLS page of the MFD.

The flight crew must maintain the default settings during all phases of flight, except in the following conditions:

- If airport data is missing from the TAWS database, and if the aircraft is within 15 nm from that airport, or

L2 When airport or terrain data is not yet included in the database, the TCF envelope cannot be defined. The TAWS function uses the lowest map resolution, due to the fact that no airport is detected. Therefore, the TAWS may trigger early and unexpected TAD alerts.

L1 - For specific approach procedures that have been identified as potentially producing erroneous terrain alerts.

● **In this case, apply the following procedure:**

TERR SYS button.....OFF

L2 *Set the TERR SYS button to OFF on the SURV/CONTROLS page of the MFD.*
The Terrain Awareness and Display (TAD) and Terrain Clearance Floor (TCF) modes are inhibited.

TCAS

Applicable to: ALL

The Traffic Collision Avoidance System (TCAS) triggers the following aural and visual alerts:

- Traffic Advisory (TA)
  A TA indicates a possible collision threat.
- Resolution Advisory (RA).
  A RA indicates that there is a high threat of collision.

For more information on the TCAS , *Refer to DSC/34/TCAS* .

OPERATION RECOMMENDATIONS

In order to avoid RA s triggering, the flight crew should limit the vertical speed during the last 2 000 ft of a climb or a descent.

L2 *The flight crew should limit the vertical speed to 1 500 ft/min during the last 2 000 ft of a climb or a descent, particularly when the other aircraft converges in altitude and attempts to level off 1 000 ft above or below the altitude target.*

L1 The flight crew should manually select TA ONLY mode, if:
- There is an engine failure
- The aircraft is dispatched with the landing gear down
- Operators have identified specific airports or procedures, for which RA s that are not appropriate may be triggered: For example, parallel runways that are next to each other, converging runways, or low terrain along the final approach.

For more information on the procedures, in the case of TCAS alert:
- *Refer to PRO/ABN/34-Surveillance/Traffic Advisory Alert*
- *Refer to PRO/ABN/34-Surveillance/Resoluation Advisory Alert* .

For additional training-oriented information, *Refer to FCTM/SI-60-GTECH General* .

ADS-B

Applicable to: ALL

AUTOMATIC DEPENDENT SURVEILLANCE - BROADCAST (ADS-B)

In some cases, the ATC ground stations can receive non valid data from the ADS-B function. Therefore, the air traffic controller may ask the flight crew to stop the transmission of the ADS-B data (e.g. the air traffic controller requests "STOP ADS-B TRANSMISSION" or "STOP ADS-B ALTITUDE TRANSMISSION").
The flight crew cannot switch off the ADS-B automatic data transmission independently of the XPDR. An operative XPDR is mandatory to maintain correct TCAS operations.
The flight crew must refer to local Aeronautical Information Publication (AIP) to apply alternate procedure when the air traffic controller requests to stop ADS-B transmission.

APU START ON BATTERIES

Applicable to: ALL

The flight crew must apply this procedure when the APU is started on ground using the batteries.

C/B 2WF, C/B 2WC, C/B 4WF, C/B 2WD1, C/B 2WD4 [Emergency Supply Center in upper avionics bay].....CHECK PUSHED

L2 *When only the batteries supply the electrical network, the power supply of the APU SQUIB cannot be verified during the fire test. As a result, the flight crew must ensure that the circuit breakers (C/B) that protect the power supply of the APU fire detection and extinguishing systems are correctly engaged.*

The circuit breakers (C/B) are located on the Emergency Supply Center:
- *Right door: Position of the C/Bs is: C/B 2WF (2060), C/B 2WC (2169), C/B 4WF (2160)*
- *Left door: Position of the C/Bs is: C/B 2WD1 (0349), C/B 2WD4 (0344).*

L1 DISPLAY SD ON MFD: PRESS 3 TIMES THE DU RECONF pb

L2 *When only the batteries supply the electrical network, only the MFD display on the CAPT side and the EWD display are available. Therefore, the flight crew must press the DU RECONF pb (3 times) on the CAPT side, to display the SD page on the MFD display .*

L1 APU SD page..... SELECT

L2 *When only the batteries supply the electrical network, to select the APU SD page, the flight crew must press and maintain the ALL pb on the ECP until the APU SD page appears.*

L1 APU MASTER SW pb-sw .....ON
APU START pb .....ON

L2 *Note: If the APU start failed, Refer to APU Start Limitation.*

L1 ● **When the APU is AVAIL**
Fire TEST pb ..... PRESS

L2 *When the aircraft is supplied by batteries, the APU SQUIB light is not powered. In this case, if the TEST pb is pressed, the APU SQUIB will not come on. Therefore, when the APU is available, the flight crew must perform the fire test to verify the availability of the fire extinguishing system.*

L1 SOP..... RESUME

L2 *After APU start, resume normal SOP, Refer to PRO-NOR-SOP-40-GOIS OIS Preparation_OIS Start .*

Intentionally left blank

MANUAL ENGINE START

Applicable to: ALL

OVERVIEW

The flight crew normally uses automatic starting to start an engine.

However, a manual starting can enable to start an engine when an automatic start is aborted due to:

- Degraded bleed performance due to hot conditions, or at high-altitude airfields, or
- An engine with a reduced EGT margin in hot conditions or at high-altitude airfields, or
- Low performance of the external pneumatic power units.

The flight crew must closely monitor the manual start sequence due to the FADEC authority that is reduced compared with an automatic engine start.
For more information on engine starting in manual mode, *Refer to DSC-70-80-30-30 Manual Starting* .
For additional training-oriented information, *Refer to FCTM/NO-80 Manual Engine Start* .

PROCEDURE

THR LEVERS ..... IDLE

CAUTION	*The engines start regardless of the thrust lever position. If the thrust levers are not set to IDLE, the thrust rapidly increases to the corresponding thrust lever position, causing a hazardous situation.*

ENG START selector ..... NORM THEN IGN START

The ENG SD page appears, and all pack valves close.

Note: After 30 s , if the ENG MAN START pb-sw is not set to ON, the pack valves open again.

ENG MAN START pb-sw .....ON

Do not set the ENG MAN START pb-sw to ON before the EGT value appears on the ENG SD page.

- **On the ENG SD page:**
  START VALVE.....CHECK IN-LINE
  OIL PRESSURE INCREASE.....CHECK
  N2 INCREASE .....CHECK

- **When N2 is at or above 20 % for 20 s :**
  ENG MASTER lever .....ON
  CHRONO..... START
  The F/O starts timing in order to monitor the light-up delay.

- **On the ENG SD page:**
  IGNITERS A AND B INDICATIONS..... CHECK
  FF INCREASE ..... CHECK
  - **20 s maximum after ENG MASTER lever is set to ON:**
    N1 AND EGT INCREASE ..... CHECK

- **When N2 is at, or above 59 % :**
  - **On the ENG SD page:**
    IGNITER INDICATION.....CHECK OFF
    START VALVE.....CHECK CROSS LINE
    MAIN AND SECONDARY ENGINE PARAMETERS.....CHECK NORMAL

ENG MAN START pb-sw ..... OFF
ENG START selector .....NORM

ENGINE START WITH GROUND PNEUMATIC POWER

Applicable to: ALL

BEFORE CONNECTING GROUND PNEUMATIC POWER

PACKS 1 & 2.....OFF

L2 *Packs are set to off to prevent any possible contamination of the packs by the ground pneumatic power.*

L1 BEFORE ENGINE START

APU BLEED pb-sw ..... OFF

L2 *The APU BLEED pb-sw is set to off to prevent multiple bleed sources that may result in adverse effect on the bleed system.*

L1 ALL ENG BLEED pb-sw ..... OFF

L2 *Simultaneous use of the external pneumatic power and the engine bleed is prohibited to prevent any adverse effect on the bleed system.*

L1 EXT PNEUMATIC PWR.....CONNECT

L2 *Two ground pneumatic units may be used in parallel, if the pressure/flow relation is expected to be marginal.*

L1 BLEED PRESS > 25 PSI.....CHECK

L2 *The recommended starter air supply pressure is 25 PSI, when the start valve is open.*

L1 WHEN CLEARED TO START

ENGINE 1 OR 2..... START

Use the normal engine start procedure.

L2 *For any operational reason, any engine can be started first.*

L1 **FOR OTHER ENGINES START**

If the external electrical power supplies the aircraft (e.g. the engines are started with the ground pneumatic power because the APU is inoperative), start a second engine before disconnecting the external electrical power.

L2 This ensures that the full aircraft network is supplied.

L1 ■ **If ground pneumatic power is used to start the other engines:**

ENGINE (ONE BY ONE).....START

Use the normal engine start procedure.

L2 *Start the engines one by one, if ground pneumatic units air supply pressure is not sufficient.*

L1 EXT PNEUMATIC PWR.....DISCONNECT

■ **If the CROSSBLEED ENGINE START procedure is used to start the other engines:**

EXT PNEUMATIC PWR.....DISCONNECT

L2 *The simultaneous use of the external pneumatic power and the engine bleed is prohibited.*

L1 ENG (AVAIL) BLEED.....ON
XBLEED.....AUTO
SECOND ENGINE.....START

It is recommended to start the engine on the same side. With one engine at idle, the starter air supply pressure shall be between 28 to 30 PSI, which is sufficient to start another engine. Therefore, it is not necessary to increase the thrust of the supplying engine. The flight crew can keep the thrust lever of the running engine at idle detent.

● **When two engines are avail:**

ENG (AVAIL) BLEED.....ON
OTHER ENGINES.....START

The flight crew can keep the thrust lever of the running engines at idle detent. The bleed air pressure is sufficient to start the two remaining engines at the same time.

AFTER ALL ENGINES START

ALL ENG BLEEDS.....ON
PACKS 1 & 2.....ON

CROSSBLEED ENGINE START

Applicable to: ALL

CAUTION	The simultaneous use of engine bleed supply and external pneumatic power supply is prohibited.

EXT PNEUMATIC PWR.....DISCONNECT

BEFORE START

ALL ENG BLEEDS.....ON
X BLEED.....AUTO

WHEN CLEARED TO START

SECOND ENG.....START

It is recommended to start the engine on the same side. With one engine at idle, the starter air supply pressure shall be between 28 to 30 PSI, which is sufficient to start another engine. Therefore it is not necessary to increase thrust of the supplying engine. The thrust lever of the running engine can be kept at the idle detent.

- **When two engines are avail:**
  OTHER ENG_S .....START

  The thrust lever of the running engines can be kept at the idle detent. The bleed air pressure is sufficient to start the two remaining engines at the same time.

- **When all engines are started:**
  PACK 1+2.....ON

START VALVE MANUAL OPERATION

Applicable to: ALL

Advise ground crew to prepare for manual start valve operation.

WARNING	Before starting an engine with manual operation of the start valve, the adjacent engine must be shutdown to ensure the security of the ground crew. The access to the start valve of the affected engine may be in the danger area of the adjacent running engine.

RMP CAB .....SELECT

The flight crew can also use the cockpit handset to establish communication with ground crew on the engine.

COM WITH GND PERSONNEL.....ESTABLISH

- **When ground crew is ready:**
  ENG START selector .....IGN START
  ENG (AFFECTED) MASTER sw .....ON
  START VALVE.....REQUEST OPEN

  The ground crew must maintain the valve in the OPEN position until the engine is started. If not, the start valve closes.

- **When N2 is at 58%:**
  START VALVE.....REQUEST CLOSE
  Resume normal procedure.

ENGINE START WITH ELECTRICAL EXTERNAL POWER

Applicable to: ALL

Start two engines before disconnecting the external electrical power.

L2 *This ensures that the full aircraft network is supplied.*

Intentionally left blank

GROUND ICE SHEDDING PROCEDURE IN CASE OF FREEZING FOG

Applicable to: ALL

OVERVIEW

When taxiing in freezing fog conditions, if temperature is less than +3 °C (37 °F), ice may accumulate on the engines fans.
The ice accretion depends on the total taxi time during which the engines are running on ground, at or around idle (e.g. during taxi) in freezing fog conditions.
The total taxi time is the cumulative time of the taxi-in time of the previous flight and the taxi-out time of the next flight, provided the freezing fog or icing conditions persisted between taxi-in and taxi-out.
In order to shed the ice, the flight crew must apply the following procedure at least every 30 min of total taxi time.

TAXI-IN

Because it is necessary to determine the remaining taxi-out time that is allowed for the next flight, the flight crew must record in the logbook the taxi-in time in freezing fog conditions.

TAXI-OUT

It is recommended to estimate with the ATC the duration of the taxi-out time in order to assess the total taxi time (i.e. taxi-in + taxi-out).
The flight crew must take into account the taxi-in time in freezing fog conditions only if the ground crew did not inspect engine icing and/or did not manually deice the engine in accordance with AMM .
If the ground crew inspected engine icing and/or manually deiced the engine in accordance with the AMM , the flight crew can consider the total taxi time of 30 min as available for the taxi-out time.
Additionally, the flight crew must assess if the ground surface and the environment permit the application of the procedure, specifically with regards to:

- Slippery runway surfaces
- Jet blast, *Refer to PRO-NOR-SOP-80 Ground Run Up - Danger Areas*
- Snow and ice ingestion on the edge of the taxiway
- Airport noise restrictions

● **If the total taxi time is expected to be less than 30 min :**

● **Apply the following ice shedding procedure, if ground surface and environment permit, within 5 min prior takeoff or when lined up, just prior takeoff:**
ATC..... NOTIFY
PARK BRK or brake with pedals .....
..... ON

THRUST LEVERS..... 60 % N1 momentarily

Accelerate the engines momentarily for a short run-up to 60 % N1.
Apply the thrust on two symmetric engines at a time (i.e. 1 and 4, 2 and 3).

CAUTION	*Pay particular attention to the aircraft movement during this procedure. If during thrust increase, the aircraft starts to move, immediately retard the thrust levers to IDLE.*

If the aircraft moves, apply the thrust on only one engine at a time.

- **If the total taxi time is expected to be more than 30 min :**
  - **Apply the following ice shedding procedure, if ground surface and environment permit, at least every 30 min of total taxi time:**

ATC..... NOTIFY
PARK BRK or brake with pedals ..... ON
THRUST LEVERS..... 60 % N1 momentarily

Accelerate the engines momentarily for a short run-up to 60 % N1.
Apply the thrust on two symmetric engines at a time (i.e. 1 and 4, 2 and 3).

CAUTION	*Pay particular attention to the aircraft movement during this procedure. If during thrust increase, the aircraft starts to move, immediately retard the thrust levers to IDLE.*

If the aircraft moves, apply the thrust on only one engine at a time.

  - **When lined up, just before takeoff:**

ATC..... NOTIFY
PARK BRK or brake with pedals ..... ON
THRUST LEVERS..... 60 % N1 momentarily

Accelerate the engines momentarily for a short run-up to 60 % N1.
Apply the thrust on two symmetric engines at a time (i.e. 1 and 4, 2 and 3).

CAUTION	*Pay particular attention to the aircraft movement during this procedure. If during thrust increase, the aircraft starts to move, immediately retard the thrust levers to IDLE.*

If the aircraft moves, apply the thrust on only one engine at a time.

- **If the preceding ice shedding procedure cannot be applied within 30 min of total taxi time (e.g. ground surface and environment does not permit):**

  Request that ground crew inspects engine icing and if necessary manually deices the engine in accordance with the AMM .

Intentionally left blank

Overview

OVERVIEW

Applicable to: ALL

For flight operations in icing conditions, *Refer to PRO-SUP-30-A Operations in Icing Conditions* .
For ground operations on contaminated runways, *Refer to PRO-SPO-FCR Taxi* .
For ground operations in freezing fog, *Refer to PRO-SUP-70-20 Ground Ice Shedding Procedure In Case Of Freezing Fog* .
For altitude correction in low temperature conditions during approach, *Refer to PER-OPD-ATR Altitude Temperature Correction For Low Altitude Use* .
In cold weather conditions, the flight crew must use the cold weather procedures for the preparation, and ground operation of the aircraft.
Depending on the deicing equipment available at the airport (fin partially deiced), the flight crew must use a specific flight preparation procedure (*Refer to PRO-SUP-91-10-10 Fin partially deiced*).
When the cold weather procedures are performed, the flight crew can continue to operate the aircraft according to the standard operating procedures.

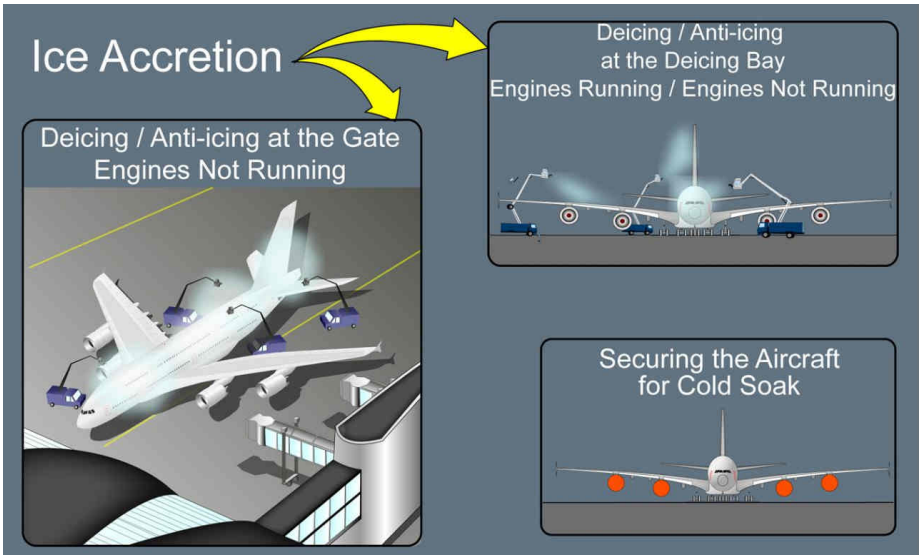
Ice accretion can occur, when:
- The air temperature is below, or near 0 °C , with precipitation, or condensation
- The aircraft is exposed to moisture, and the aircraft has been:
  - Cold soaked during a flight at high altitude, or
  - Refueled with cold fuel, or
  - Exposed to low overnight temperatures.

In one of these situations, and depending on the airport, the flight crew must:
- Deice/anti-ice the aircraft at the gate, with no engine running, or
- Taxi to the deicing bay for deicing/anti-icing with engines running, or
- Taxi to the deicing bay for deicing/anti-icing with engines not running.

Note: - *In cold weather conditions, the crewmembers should maintain the doors closed as often as possible, in order to avoid disturbance of the temperature regulation in the cockpit and in the cabin areas near the doors.*
- *The safety exterior inspection, the preliminary cockpit preparation, the exterior inspection, and the cockpit preparation procedures for cold weather, are the same for the deicing/anti-icing at the gate, and for the deicing/anti-icing at the deicing bay.*

After the flight, the aircraft must be secured for cold soak.

Cold Weather Conditions



Deicing/Anti-icing at the Gate - Engines Not Running

SAFETY EXTERIOR INSPECTION

Applicable to: ALL

SAFETY EXTERIOR INSPECTION SOP.....PERFORM

For a detailed description of the safety exterior inspection SOP, Refer to associated procedure .

- **In addition, apply the following procedure:**

  APU AIR INTAKE..... CLEAR OF ICE AND SNOW

  The APU air intake is visible behind the horizontal stabilizer, on the RH side of the aircraft.

  PACK RAM AIR INLET AND PACK RAM AIR OUTLETS.....
  .....CLEAR OF ICE AND SNOW

  OUTFLOW VALVE..... CLEAR OF ICE AND SNOW

When the APU air intake, the pack ram air inlet and outlets, and the outflow valve are not clear of ice and snow, request for deicing, as necessary.

PRELIMINARY COCKPIT PREPARATION

Applicable to: ALL

PRELIMINARY COCKPIT PREPARATION SOP..... PERFORM

For the detailed description of the cockpit preparation SOP, Refer to associated procedure .

- **In addition, apply the following procedure:**

  PROBE/WINDOW HEAT P/B..... ON

  When no engine is started, window heating operates when the PROBE/WINDOW HEAT pb-sw is set to ON.

EXTERIOR INSPECTION

Applicable to: ALL

EXTERIOR INSPECTION SOP.....PERFORM

For a detailed description of the exterior inspection SOP, Refer to associated procedure .

- **During exterior inspection, apply the following procedure:**

  SURFACES..... CLEAR OF FROST, ICE, AND SNOW

  The following surfaces must be cleared of frost, ice, and snow:
  - *Leading edges and upper surfaces of the wings*
  - *Vertical and horizontal stabilizers*

- *All control surfaces*
- *Slats and flaps.*

Thin hoarfrost is acceptable on the upper surface of the fuselage. On the lower side of the wing tank area, a layer of frost thinner than 3 mm (0.12 in) does not penalize aircraft performance during takeoff.

Note: Thin hoarfrost is a white crystalline deposit that develops uniformly on the exposed aircraft surfaces during cold and cloudless nights. Below the hoarfrost layer, it is possible to distinguish the surface features (e.g. lines or markings).

EQUIPMENT..... CLEAR OF FROST, ICE, AND SNOW

The following equipment must be cleared of frost, ice, and snow:
- *Landing gear equipment: Lever locks, tires, and landing gear doors*
- *Engine inlets, inlet lips, fans (check that the fans can rotate), spinners, fan exhaust ducts, reverser equipment*
- *Drains, bleeds, probes, (pitots, static ports, TAT sensors, angle-of-attack sensors)*
- *Fuel tank ventilation*
- *Radome*
- *Commercial water supply must not be frozen, and must have been refilled. Before cold soak, the water supplies must be emptied.*
- *Air/hydraulic heat exchanger inlet.*

COCKPIT PREPARATION

Applicable to: ALL

COCKPIT PREPARATION SOP.....PERFORM

For a detailed description of the cockpit preparation SOP, Refer to associated procedure .

DEICING/ANTI-ICING AT THE GATE

Applicable to: ALL

The captain must decide whether or not to deice/anti-ice the aircraft, and to repeat the operation, as necessary.
The flight crew must ensure that the ground personnel use deicing/anti-icing fluids, in accordance with the applicable Operator's requirements, and with the Aircraft Maintenance Manual instructions.

CAUTION	- Check that the HP or LP ground connectors do not supply external air to the aircraft - If anti-icing must be performed after deicing, the ground personnel must deice the surfaces with a hot fluid mixture before applying a new layer of anti-icing fluid - Avoid indiscriminate use of deicing/anti-icing fluid, or its ingestion by the engine or the APU - Do not move slats or flaps, or flight control surfaces if they are not free of ice - The aircraft must be deiced/anti-iced symmetrically: Both sides of the aircraft must be deiced/anti-iced completely.

Note: *When possible, do not disconnect the external power units until the aircraft is thoroughly deiced. If the external power units have to be disconnected in order to move the aircraft, reconnect the external power units before turning the APU off.*

● **BEFORE FLUID SPRAYING:**

WINDOWS & DOORS..... CLOSE
GEAR PINS and COVERS.....REMOVE
COMMUNICATION WITH GROUND PERSONNEL..... ESTABLISH
PARK BRK.....ON
APU BLEED..... OFF

● **If at least two external power units electrically supply the aircraft:**

APU MASTER SW..... OFF

L2 *If the external power units are not available, the flight crew can maintain the APU on in order to electrically supply the aircraft.*

L1 DITCHING pb ..... ON

L2 *Setting the DITCHING pb to ON closes the following:*

L3
- *The outflow valves*
- *The overboard valve*
- *Both pack valves*
- *All the cargo isolation valves*
- *The pack ram air inlet and outlets*
- *The two emergency RAM air inlets.*

L1 *This prevents the deicing fluid from entering the aircraft.*
All cabin fans stop.
The avionics ventilation remains available, when the avionics ventilation blowing fans are operative.

MAXIMUM 30 MIN WITH DITCHING P/B ON

On ground, with passengers on board, it is not recommended to exceed 30 min without air conditioning, because passenger comfort may be affected.

- **When the aircraft is ready for spraying:**

  FLUID SPRAYING.....REQUEST

- **AFTER FLUID SPRAYING:**

DITCHING pb .....OFF
OUTFLOW VALVES.....CHECK OPEN

To avoid any unexpected pressurization, check on the CAB PRESS SD page that the four outflow valves are open.

APU.....AS RQRD

- **At least 1 min after APU start or fluid spraying:**

  APU BLEED.....AS RQRD

  Note: *If the fuselage was sprayed, there is a risk of fluid ingestion by the APU air intake resulting in odors or smoke alerts. Therefore, the flight crew should consider a takeoff with APU bleed off.*

EXT PWR.....AS RQRD
GROUND EQUIPMENT.....REMOVE
PROBE/WINDOW HEAT pb .....AUTO
DEICING/ANTI-ICING REPORT.....RECEIVED

The information from the ground personnel who performed the deicing/anti-icing, and the post-application check must include:

- *The type of fluid used*
- *The ratio of fluid to water (e.g. 75/25)*
- *The time of the holdover beginning*
- *The result of the post-application check: "Aircraft critical parts are clean".*

BEFORE PUSHBACK OR START

Applicable to: ALL

BEFORE PUSHBACK OR START SOP.....PERFORM

For a detailed description of the after start SOP, Refer to associated procedure .

- **The flight crew should perform the after start SOP, except the following:**

PROBE/WINDOW HEAT pb ..... AUTO

L2 *When at least one engine is started, window heating operates under automatic control.*

L1 RUDDER TRIM : DO NOT MOVE

L2 *The flight controls can only be moved, when the aircraft is thoroughly deiced.*

L1 FLAPS LEVER : DO NOT MOVE

L2 *The flight controls can only be moved, when the aircraft is thoroughly deiced.*

L1 FLIGHT CONTROL SURFACES : DO NOT MOVE

L2 *The flight crew must not perform the flight controls check until the aircraft is thoroughly deiced.*

L1 NORM C/Ls : DELAY UNTIL ACFT DEICED

L2 *Delay the AFTER START checklist until the aircraft is thoroughly deiced.*

TAXI TO DEICING BAY

Applicable to: ALL

ANTISKID INHIBITED BELOW 4 KT

PAX..... NOTIFY

DEICING/ANTI-ICING AT THE DEICING BAY

Applicable to: ALL

The captain must decide whether or not to deice/anti-ice the aircraft, and to repeat the operation, as necessary.

The flight crew must ensure that the ground personnel use deicing/anti-icing fluids, in accordance with the applicable Operator's requirements, and with the Aircraft Maintenance Manual instructions.

CAUTION	- Check that the HP or LP ground connectors do not supply external air to the aircraft - If anti-icing must be performed after deicing, the ground personnel must deice the surfaces with a hot fluid mixture before applying a new layer of anti-icing fluid - Avoid indiscriminate use of deicing/anti-icing fluid, or its ingestion by the engine or the APU - Do not move slats or flaps, or flight control surfaces if they are not free of ice - The aircraft must be deiced/anti-iced symmetrically: Both sides of the aircraft must be deiced/anti-iced completely.

● **BEFORE FLUID SPRAYING:**

COMMUNICATION WITH GROUND PERSONNEL..... ESTABLISH
PARK BRK..... ON
APU BLEED..... OFF
DITCHING pb ..... ON

L2 *Setting the DITCHING pb to ON closes the following:*
L3
- *The outflow valves*
- *The overboard valve*
- *Both pack valves*
- *All the cargo isolation valves*
- *The pack ram air inlet and outlets*
- *The two emergency RAM air inlets.*

L1 *This prevents the deicing fluid from entering the aircraft.*
All cabin fans stop.
The avionics ventilation remains available, when the avionics ventilation blowing fans are operative.

MAXIMUM 30 MIN WITH DITCHING P/B ON

On ground, with passengers on board, it is not recommended to exceed 30 min without air conditioning, because passenger comfort may be affected.

● **When the aircraft is ready for spraying:**

FLUID SPRAYING.....REQUEST

● **AFTER FLUID SPRAYING:**

DITCHING pb .....OFF

Ground Operations

GROUND OPERATIONS AT AIRPORTS COVERED WITH VOLCANIC ASH, SAND, OR DUST

Applicable to: ALL

Volcanic ash has very abrasive particles that can significantly damage aircraft parts and degrade the operation of aircraft systems.
If possible, Operators should avoid airports that are covered with volcanic ash.
If it is not possible to avoid these airports, Operators must apply the following procedures.
If Operators operate on airports covered with sand or dust, they can apply most of the following ground operations procedures in order to avoid contamination of the aircraft systems, based on their experience and on the amount of deposit.

PRELIMINARY COCKPIT PREPARATION

Applicable to: ALL

PRELIMINARY COCKPIT PREPARATION SOP..... PERFORM

For a detailed description of the preliminary cockpit preparation SOP, Refer to associated procedure .

- **In addition, apply the following procedures:**

APU..... DO NOT USE

L2 *Request ground power for air conditioning and electricity. If ground power is not available, the APU should be used to start the engines, but should not be used for anything else.*

L1 WINDSHIELD WIPERS.....DO NOT USE

L2 *Do not use windshield wipers to remove volcanic ash or any particles.*

L1 **PRELIMINARY PERFORMANCE DETERMINATION**

BRAKING PERFORMANCE.....CONSIDER PENALTY

L2 *A layer of volcanic ash on the runway may degrade braking performance. The performance penalties for takeoff on runways with:*
- *Dry volcanic ash, are similar to the performance penalties for takeoff on wet runways*
- *Wet volcanic ash, are similar to the performance penalties for takeoff on runways covered with slush.*

L1 Consider a takeoff with the packs set to OFF, in order to avoid contamination of the air conditioning system.

EXTERIOR INSPECTION

Applicable to: ALL

EXTERIOR INSPECTION SOP.....PERFORM

For a detailed description of the exterior inspection SOP, Refer to associated procedure .

- **During the exterior inspection, carefully check the following:**

SURFACES AND EQUIPMENT.....CHECK FREE OF DEPOSITS

The ground crew must remove volcanic ash, sand or dust from lubricated surfaces, and must remove all deposits that could:
- *Penetrate seals*
- *Enter the engine gas path, air conditioning system, air data probes, access doors and panels, and other openings on the aircraft.*

ENGINE/APU INLETS.....CHECK FREE OF DEPOSITS

L2 *Inspect the inlets, and make sure that the ground crew removes all deposits. The ground crew should also remove the deposits from the area that is within 25 ft of the engine inlets.*

BEFORE PUSHBACK OR START

Applicable to: ALL

BEFORE PUSHBACK or START SOP.....PERFORM

For a detailed description of the before pushback or start SOP, Refer to associated procedure .

- **In addition, pay attention to the following:**

BRAKING PERFORMANCE.....CONSIDER PENALTY

L2 *A layer of volcanic ash on the runway may degrade braking performance. The performance penalties for takeoff on runways with:*
- *Dry volcanic ash, are similar to the performance penalties for takeoff on wet runways*
- *Wet volcanic ash, are similar to the performance penalties for takeoff on runways covered with slush.*

L1 Consider a takeoff with the packs set to OFF, in order to avoid contamination of the air conditioning system.

ENGINE START

Applicable to: ALL

Use external pneumatic power to start the engines, if available.

For a detailed description of the manual engine start, *Refer to associated procedure* .

ALL ENGINES.....CRANK

Before engine start, ventilate all engines for 2 min by dry-cranking at the maximum motoring speed to remove any deposit from the booster area.

TAXI

Applicable to: ALL

TAXI SOP.....PERFORM

For a detailed description of the taxi SOP, Refer to associated procedure .

- **After brake release, apply the following procedure:**

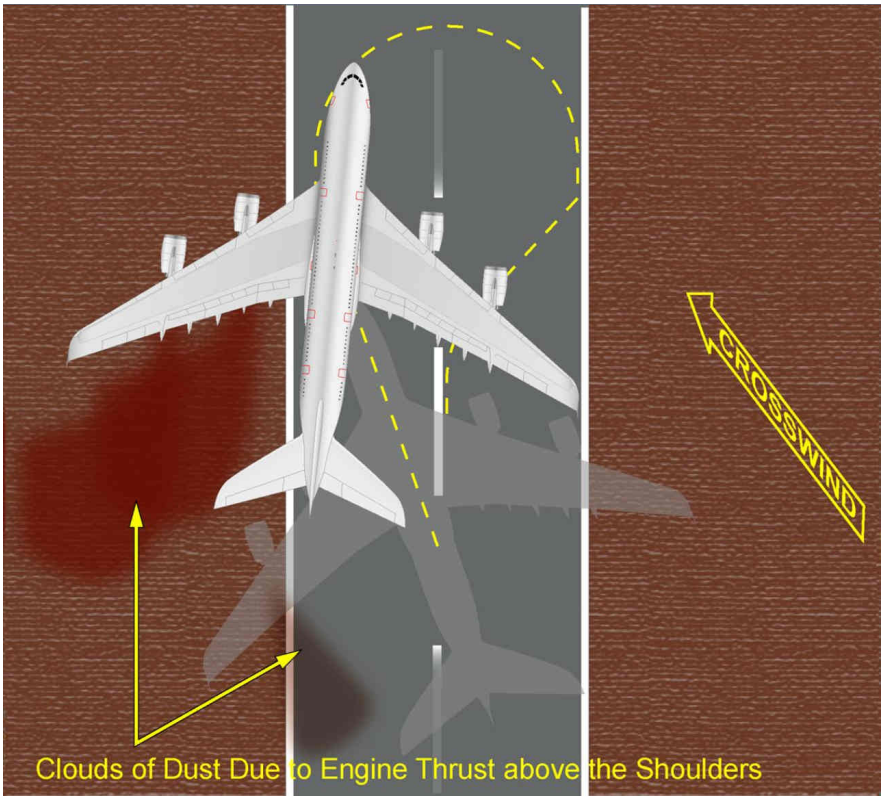
THRUST LEVERS.....MOVE FWD SMOOTHLY then SET TO IDLE

L2 *Smoothly move the thrust levers forward to the minimum required position, in order to begin moving the aircraft.*
Avoid sharp and high-speed turns.
Perform an all-engine taxi to minimize the thrust on each engine.

L1 ENGINE BLEED.....OFF

L2 *Keep the engine bleed valves closed during taxi, particularly in volcanic ash conditions.*

L1 In the case of crosswind when performing a 180 ° turn on the runway, start to turn with the nose downwind in order to prevent ash, sand, or dust ingestion.



TAKEOFF

Applicable to: ALL

Before starting the takeoff roll, wait for volcanic ash, sand, and dust to settle on the runway.
If possible, perform a rolling takeoff.
TAKEOFF SOP..... PERFORM

For a detailed description of the thrust application for takeoff, Refer to associated procedure .

Consider a takeoff with the packs set to OFF, in order to avoid contamination of the air conditioning system.

LANDING

Applicable to: ALL

L2 *Note: Volcanic ash deposits on the windshield and/or on the landing lights may significantly reduce the flight crew's visibility during approach and landing. Therefore, consider performing a diversion to an airport where AUTOLAND is possible.*

L1 LANDING SOP.....PERFORM

For a detailed description of the landing SOP, Refer to associated procedure .

- **In addition, pay attention to the following:**

REVERSERS.....AS RQRD

L2 *If maximum reverse thrust is necessary, apply reverse thrust at Main Landing Gear (MLG) touchdown. Limit the use of thrust reversers as much as possible, because the reverse air flow can stir the volcanic ash, sand, or dust, and reduce visibility.*

L1 BRAKING PERFORMANCE.....CONSIDER PENALTY

L2 *A layer of volcanic ash on the runway may degrade braking performance. The performance penalties for landing on runways with:*

- *Dry volcanic ash, are similar to the performance penalties for landing on wet runways*
- *Wet volcanic ash, are similar to the performance penalties for landing on runways covered with slush.*

SECURING THE AIRCRAFT

Applicable to: ALL

- **After turning off all bleeds and before turning off AC power, apply the following procedure:**

DITCHING pb .....ON

L2 *When set to ON, the following will close, in order to protect the aircraft from volcanic ash, sand, or dust ingestion:*

L3
- *The outflow valves*
- *The overboard valve*
- *Both pack valves*
- *All cargo isolation valves*
- *The pack ram air inlets and outlets*
- *Both emergency ram air inlets.*

L1 ● **After turning off the batteries, apply the following procedures:**

DITCHING pb .....OFF

L2 *When set to OFF, all the applicable valves will open, at the next power-up.*

L1 PROTECTIVE COVERS.....INSTALL

L2 *Install protective covers and plugs to protect the aircraft from volcanic ash, sand, or dust.*

Flight Operations

MISC VOLCANIC ASH ENCOUNTER

Applicable to: ALL

Volcanic ash has very abrasive particles that can significantly damage aircraft parts and degrade the operation of aircraft systems.
Avoid flight in active volcanic areas.
If a volcanic eruption is reported, change the flight route, in order to avoid the area because volcanic dust can spread over several hundred miles. When possible, stay on the upwind side of the volcano, at a distance of atleast 20 nm.

The following may be indications that the aircraft is flying in a volcanic ash cloud:
- Dust in the cockpit
- An acrid odor, similar to electrical smoke
- St Elmo's fire (i.e. a bright white and blue glow appears on the wings)
- Bright white or orange sparks in the engine inlets
- Sharp and distinct beams from the landing lights
- Multiple engine malfunctions (e.g. increased EGT, decreased power, stall, or flameout)
- Airspeed fluctuations
- Reduced visibility.

Continued on the following page

MISC VOLCANIC ASH ENCOUNTER (Cont'd)

180° TURN.....INITIATE

L2 *The performance of a 180 ° turn will usually enable the aircraft to exit the volcanic ash clouds as quickly as possible, because volcanic ash clouds can extend for hundreds of nautical miles.*

L1 ATC.....NOTIFY
A/THR..... OFF

L2 *This action prevents thrust variations due to the use of autothrust.*

L1 THRUST (IF CONDS PERMIT)..... REDUCE

L2 *A decrease in thrust helps to maintain the engine stall margin by reducing the amount of volcanic ash ingestion and limiting the EGT . It also limits the accumulation of molten ash on the turbine vanes.*
Do not climb, because this increases the EGT .

L1 CREW OXY MASKS..... ON / 100% / EMER
CABIN CREW.....ADVISE
PAX OXY MASK MAN ON.....AS RQRD

L2 *Oxygen masks may be necessary depending on the cabin contamination.*

L1 A-ICE AUTO MODE.....OFF
ENG A-ICE.....ON
WING A-ICE.....ON
AIR FLOW.....HI

L2 *Maximum air bleed provides the engines with an additional stall margin.*

L1 *Note: If a CARGO VENTILATION system is installed, the flight crew should turn off the CARGO ISOL VALVES pb-sw to prevent the ECAM from triggering a cargo smoke warning.*

APU.....AS RQRD

L2 *It may be necessary to turn on the APU for a starter–assisted engine relight.*

L1 ENG PARAMETERS..... MONITOR

L2 *Carefully monitor the EGT to prevent the engines from exceeding EGT limits.*

Note: To prevent the engines from exceeding EGT limits, it may become necessary to perform a precautionary engine shutdown. In this case:
- *Restart the engines, when the aircraft is no longer flying in a volcanic ash cloud*
- *The engines may accelerate very slowly. This is not an indication of a start failure*
- *Due to the fact that the compressor and turbine blades may have been eroded, avoid sudden thrust changes. Fuel flow and the EGT may increase.*

Continued on the following page

MISC VOLCANIC ASH ENCOUNTER (Cont'd)

L1 AIR SPEED.....MONITOR

L2 *Volcanic ash may cause a blockage in the pitot probes. If speed indication is lost, or becomes unreliable, Refer to NAV ALL AIR DATA DISAGREE and apply the procedure.*

Note: Electrostatic conditions may cause communication problems.

L1 *Note: If the flight crew does not have enough visibility for approach due to windshield (window) damage, they should consider automatic landing. If automatic landing is not available, consider opening the sliding window on the PF 's side, after cabin depressurization.*

To manually depressurize the cabin:

- *Set the CABIN ALT MODE pb-sw to MAN*
- *Set the CABIN ALT TRGT selector to an altitude slightly above the current aircraft altitude*
- *Avoid high descend rate*
- *Open the sliding window on the PF 's side if the cabin ΔP equals 0 PSI .*

If the aircraft altitude is more than 10 000 ft , the flight crew should don the oxygen mask before cabin depressurization.
Due to increased noise level when the sliding window is open, the flight crew should pay particular attention to visual alerts.

Intentionally left blank

WEATHER RADAR

Applicable to: ALL

The weather radar is a good tool for the detection of adverse weather. This section provides recommendations on the use of the weather radar, based on a general knowledge of the radar capabilities.
For more information about the WXR , *Refer to DSC-34-20-30-10 Overview* .

The flight crew should monitor the weather, by selecting long and also short ND ranges, in order to determine the best trajectory to avoid areas of adverse weather.

- **In order to avoid thunderstorms, apply the following procedure:**
  PM EFIS CP..... ND RANGE 160 nm
  PF EFIS CP..... ND RANGE 80 nm

  To avoid a large thunderstorm, make decisions when the aircraft is at least 40 nm away from the thunderstorm.

Avoid red and magenta areas, by at least:
- 20 nm , if the aircraft is above FL 230
- 5 nm to 10 nm , if the aircraft is below FL 230 .

Note: Closely spaced, or thin lines, between color gradations usually indicate severe turbulence.

Avoid single magenta areas of turbulence that are not associated with heavy precipitation, by at least 5 nm .
Avoid penetrating a cell or clearing its top by less than 5 000 ft , because turbulence may occur at the top of the clouds.
If the top of the cell is at or above 25 000 ft , avoid overflying the cell, because turbulence may be stronger than expected.
Avoid flying under a thunderstorm, because of possible windshears, microbursts, severe turbulence, or hail.
If any doubt, prefer lateral deviation, instead of vertical deviation.

- **To better analyze the weather situation, apply the following procedure:**
  WXR MANUAL MODE..... AS RQRD

L2 *The flight crew can use the manual modes temporarily, in order to monitor thunderstorm development and to obtain the best cell echo.*

L1 WXR AUTO MODE..... SELECT

L2 *When the flight crew has completed the analysis, select the AUTO mode of the weather radar.*

Intentionally left blank

OVERVIEW

Applicable to: ALL

To display this procedure, press the ECP ABN PROC pb, then select the MISCELLANEOUS menu.

Severe turbulence causes large and abrupt changes in altitude and/or attitude, usually causes large variations in airspeed, pushes passengers and crewmembers against their seat belts, and causes loose objects to move around the aircraft.

Therefore, the flight crew should avoid areas of severe turbulence by flying the aircraft above, or around, these areas. If the flight crew cannot avoid these areas, they should expect large altitude variations, and should:

- Maintain aircraft speed in the range indicated in the following procedure
- Maintain attitude and allow altitude variations, if the flight crew manually flies the aircraft.

At the end of a flight with severe turbulence, the flight crew must make a logbook entry, in order to notify maintenance personnel that maintenance action is required.

Note: The operational recommendations for severe and extreme turbulence are identical.

MISC SEVERE TURBULENCE IN CRUISE

Applicable to: ALL

SIGNS.....ON

- **If no more restrictive speed limitation**

  MAX TURB SPEED : 300 / .85

L2 *This speed range:*
- *Protects the aircraft structure from wind gusts*
- *Maintains a buffet margin, especially during vertical wind gusts.*

L1 MIN TURB SPEED : GREEN DOT
ADJUST SPEED AS NECESSARY FOR COMFORT
AP : KEEP ON
CABIN & CKPT (LOOSE EQPT)..... SECURE

L2 *The flight and cabin crewmembers must secure all loose equipment.*

L1 SPEED BRAKES..... AS RQRD

L2 *Be prepared to use the speedbrakes, if necessary.*

L1 ● **IF EXCESSIVE THRUST VARIATIONS:**

A/THR..... DISCONNECT

L2 *Do not attempt to maintain Mach or airspeed.*

LIMITATIONS

LIMITATIONS ON ECAM

SEVERE TURBULENCE DURING APPROACH

Applicable to: ALL

In high-lift configurations, operational speeds provide sufficient stall and overspeed margins when the aircraft is flying in turbulent conditions.

A/THR..... RECOMMENDED

L2 *During the approach phase, autothrust is recommended in managed speed.*

Intentionally left blank

OVERVIEW

Applicable to: ALL

L2 For additional training-oriented information, *Refer to FCTM/SI-10-10-2 General* .

L1 To reduce the risk of a windshear encounter, the flight crew can suspect windshear by checking meteorological reports and listening to ATC reports.
In addition, there are two aircraft systems that can detect a windshear, and increase flight crew's awareness of windshear.

If windshear is detected, the Predictive Windshear System (PWS) and the PRIM s may trigger the following alerts:

- The PWS triggers predictive windshear alerts:
  - Both PFD s display the W/S AHEAD caution, or the W/S AHEAD warning
  - These alerts are associated with aural alerts
  - The ND s display the windshear location.

  For more information, *Refer to SURV / WXR / PWS* .
- The PRIM s trigger a reactive windshear warning:
  - Both PFD s display the WINDSHEAR warning, during the takeoff and landing phases
  - This warning is associated with an aural alert.

  For more information, *Refer to FLIGHT ENVELOPE / Reactive Windshear* .

SUSPECTED WINDSHEAR

Applicable to: ALL

BEFORE TAKEOFF

Delay takeoff, until weather conditions are better.

L2 *Confirm if the weather conditions are safe for takeoff by:*
- *Observation and experience*
- *Checking weather conditions.*

L1 MOST SUITABLE RUNWAY.....SELECT

L2 *Take into account the location of suspected windshear, when selecting the most suitable runway.*

L1 ● **Before starting the takeoff run:**
WEATHER RADAR.....CHECK

L2 *Press the EFIS CP WX pb to check the weather radar and the PWS display on the ND, and to ensure that there are no suspected problem areas on the flight path.*

L1 TOGA THRUST.....SELECT

L2 *Do not use reduced takeoff thrust (i.e. derate or FLEX).*

L1 SPEED and SPEED TREND.....MONITOR

L2 *During the takeoff run, carefully monitor airspeed and the airspeed trend, for early indications of windshear.*

Continued on the following page

SUSPECTED WINDSHEAR (Cont'd)

DURING APPROACH

Delay landing, until weather conditions are better, or divert to another airport.

L2 *Confirm if the weather conditions are safe for landing by:*
- *Observation and experience*
- *Checking weather conditions.*

L1 WEATHER RADAR.....CHECK

L2 *Press the EFIS CP WX pb: To check the weather radar and the PWS display on the ND, and to ensure that there are no suspected problem areas on the flight path.*

L1 MOST SUITABLE RUNWAY.....SELECT

L2 *Take into account the location of suspected windshear, when selecting the most suitable runway approach aid.*

L1 FLAPS 3 .....SELECT
MANAGED SPEED.....USE

L2 *Use managed speed during the approach phase.*
When in managed speed, the ground speed mini function provides additional speed in strong wind conditions.

L1 Both FDs.....CHECK ENGAGED

L2 *Make sure that both FDs are engaged in ILS approach modes, FPA or V/S modes.*

L1 AUTOPILOT.....ENGAGE

L2 *Engage the autopilot to ensure a more accurate approach, and to rapidly correct any deviation from the beam, when the ILS is available.*

L1 ● **If downburst is expected:**
VAPP.....INCREASE

L2 *Increase the VAPP, that appears on the MFD, up to a maximum of VLS + 15 kt.*

PREDICTIVE WINDSHEAR

Applicable to: ALL

WINDSHEAR AHEAD

Apply the precautionary steps, as indicated in the SUSPECTED WINDSHEAR procedure (*Refer to procedure*), if the PWS triggers:

- The W/S AHEAD caution on the PFD s
- The associated MONITOR RADAR DISPLAY aural alert
- The location of windshear on the ND .

Continued on the following page

PREDICTIVE WINDSHEAR (Cont'd)

WINDSHEAR AHEAD ALERT

Apply the following procedure on ground, before and during takeoff, if the PWS triggers:
- The W/S AHEAD warning on the PFDs
- The associated WINDSHEAR AHEAD, WINDSHEAR AHEAD aural alert
- The location of windshear on the ND.

■ **On ground:**

L2 *Note: If the flight crew verifies and confirms that there is no risk of windshear, they may disregard the alert, provided that:*
- *There are no other signs of possible windshear conditions*
- *The reactive windshear function is operative.*

There are reported cases that specific environments (e.g. obstacles) cause the spurious triggering of predictive windshear alerts, during either takeoff or landing. However, the flight crew must always rely on all reactive windshear (i.e. WINDSHEAR) alerts.

L1 ■ **Before takeoff:**

TAKEOFF.....DELAY

L2 *Delay takeoff, until weather conditions improve.*

L1 MOST SUITABLE RUNWAY.....SELECT

L2 *When selecting the most suitable runway, take into account the location of predicted windshear.*

L1 ■ **During the takeoff run:**

TAKEOFF.....REJECT

L2 *Predictive windshear alerts are inhibited above 100 kt, and until the aircraft reaches 50 ft.*

L1 ■ **When airborne, at initial climb:**

THR LEVERS.....TOGA

L2 It is permitted to change the slats/flaps configuration, provided that the aircraft does not enter a windshear.

L1 SRS ORDERS..... FOLLOW

L2 *Note: If the autopilot is engaged, it will disengage, when the angle-of-attack goes above alpha prot.*

Continued on the following page

PREDICTIVE WINDSHEAR (Cont'd)

L1 Apply the following procedure at landing, if the PWS triggers:
- The W/S AHEAD warning on the PFDs
- The associated GO AROUND, WINDSHEAR AHEAD aural alert
- The location of windshear on the ND.

● **At landing:**

L2 *Note: If the flight crew verifies and confirms that there is no risk of windshear, they may disregard the alert, provided that:*
- *There are no other signs of possible windshear conditions*
- *The reactive windshear function is operative.*

There are reported cases that specific environments (e.g. obstacles) cause the spurious triggering of predictive windshear alerts, during either takeoff or landing. However, the flight crew must always rely on all reactive windshear (i.e. WINDSHEAR) alerts.

L1 GO AROUND..... PERFORM

L2 *It is permitted to change the slats/flaps configuration, provided that the aircraft does not enter a windshear.*

L1 L/G UP..... SELECT
SRS ORDERS..... FOLLOW

L2 *If necessary, the flight crew may apply full backstick.*

Note:
- *If the autopilot is engaged, it will disengage, when the angle-of-attack goes above alpha prot.*
- *If the FD is not available, select an initial pitch attitude of 12.5 °. Then, if necessary, increase the pitch attitude, in order to minimize the decrease in altitude.*

REACTIVE WINDSHEAR

Applicable to: ALL

If windshear is detected, either by the systems, or by the flight crew, apply the following recovery techniques:

■ **On ground, at takeoff:**

L2 During the takeoff roll, WINDSHEAR, WINDSHEAR, WINDSHEAR alert is inhibited. Windshear recognition is based on the flight crew observation.

L1 ● **Before V1:**

If there are significant variations in airspeed, and in airspeed trend below the indicated V1, reject the takeoff.

L2 *If windshear occurs during the takeoff roll, the aircraft may reach V1 later (or sooner) than expected. The flight crew should ensure that there is sufficient runway remaining to stop the aircraft, if necessary.*

L1 ● **After V1:**

THR LEVERS.....TOGA
REACHING VR.....ROTATE NORMALLY
SRS ORDERS..... FOLLOW

■ **When airborne, during initial climb, or at landing:**

THR LEVERS AT TOGA..... SET OR CONFIRM
AP (if engaged).....KEEP ENGAGED
SRS ORDERS.....FOLLOW

L2 *If necessary, the flight crew may apply full backstick.*

Note: - *If the autopilot is engaged, it will disengage, when the angle-of-attack goes above alpha prot.*
- *If the FD is not available, select an initial pitch attitude of 12.5 ° . Then, if necessary, increase the pitch attitude, in order to minimize the decrease in altitude.*

L1 DO NOT CHANGE CONFIGURATION (SLATS/FLAPS, GEAR) UNTIL OUT OF WINDSHEAR.

CAREFULLY MONITOR FLIGHT PATH AND SPEED.

RECOVER SMOOTHLY TO CLIMB, WHEN OUT OF WINDSHEAR.

Intentionally left blank

TAXI WITH DEFLATED TIRES

Applicable to: ALL

In some situations, after a rejected takeoff or after a landing, the flight crew may need to taxi the aircraft with deflated tires.

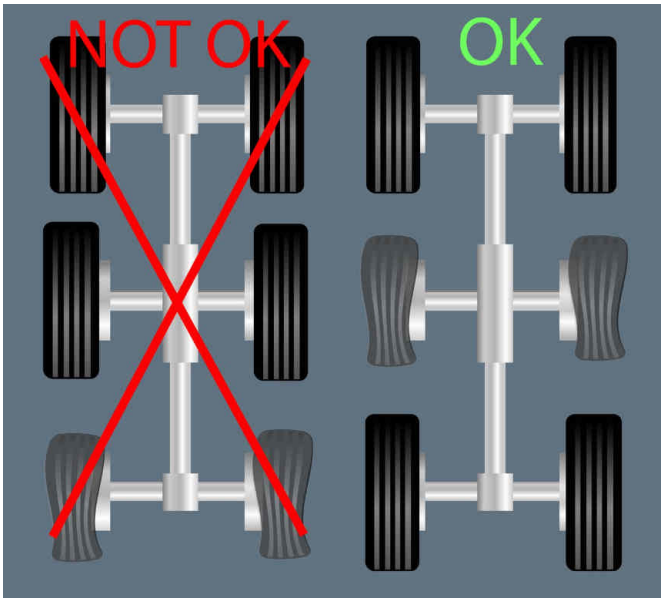
LIMITATIONS

The following limitations apply in order to be able to taxi with deflated tires:

- Maximum taxi speed: 3 kt
- Maximum nosewheel steering angle: 30 °
- Up to 9 tires can be deflated with the following maximum of deflated tires per landing gear:
  - One deflated tire on the nose landing gear, or/and
  - Two deflated tires per body landing gear provided they are not on the same axle, or/and
  - Two deflated tires per wing landing gear provided they are not on the same axle.

  Exceptions:
  - For runway vacating only: The two deflated tires on the body or wing landing gear can be on the same axle
  - For taxi: The two deflated tires can be located on the center axle of the body landing gear.

Deflated Tires Distribution Allowed for Taxi



OPERATIONAL RECOMMENDATIONS

The flight crew uses the WHEEL SD page to know the condition of each tire.

RUNWAY VACATING

Due to airport operational constraints, the flight crew can decide to vacate the runway with deflated tires or tire burst. Nevertheless, the deflated tires distribution must be in accordance with the above limitations.

TAXI

In the case of deflated tires, the flight crew can taxi the aircraft to the gate in accordance with the above limitations.
If the number or the distribution of deflated tires is not in accordance with the above limitations, the appropriate wheels must be replaced to recover an aircraft configuration allowed for taxi.
In the case of suspected tire burst, the flight crew must ask for an aircraft inspection before taxi.
If the ground crew assesses that a tire spread can damage the landing gear, the ground crew must replace the affected wheels before taxi.

GENERAL

Applicable to: ALL

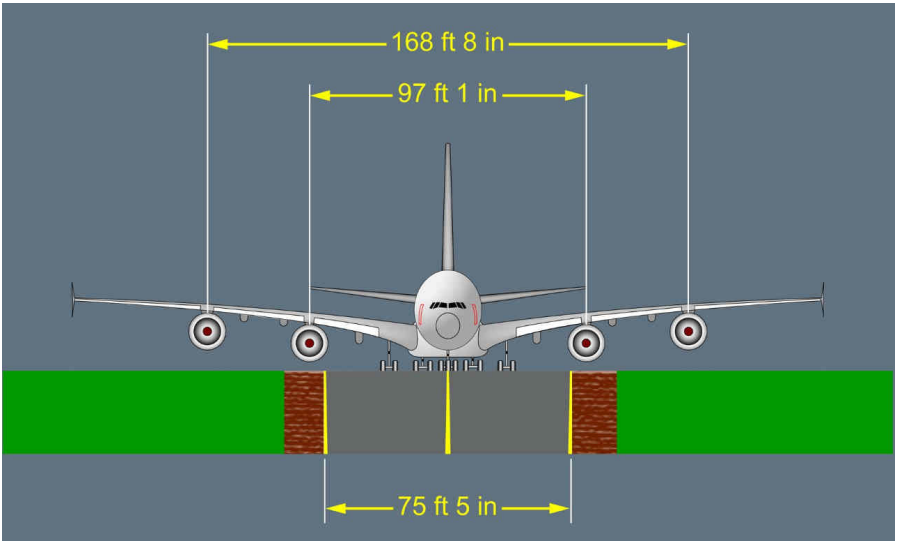
TAXIWAY CONFIGURATION

The A380 can taxi on 75 ft 5 in wide taxiways.

L2 Some states allow the A380 to taxi on taxiways narrower than 75 ft 5 in.

L1 The A380 engines extend beyond the paved area of 75 ft 5 in wide taxiways, as shown below.

A380 on 75 ft 5 in Wide Taxiway



KIND OF TAXIWAY SHOULDER

Depending on the width of the taxiway shoulders, the A380 engines may be either above:

- Stabilized surface: I.e. grass without loose gravel or asphalt
- Non-stabilized surface: I.e. natural soil, sand, grass with loose gravels, snow.

RECOMMENDATIONS

Applicable to: ALL

GENERAL RECOMMENDATIONS

At low weight (e.g. landing weight), idle thrust on the four engines is sufficient to move the aircraft. If additional thrust is needed, e.g. in the case of slope, it is recommended to apply the additional thrust only on two out of the four engines.

L2 This recommendation provides a smooth acceleration which increases passenger comfort.

L1 **OPERATIONAL RECOMMENDATIONS**

ON TAXIWAY PLUS PAVED SHOULDERS MORE THAN 180 FT WIDE

The flight crew may use any of the engines if additional thrust is needed (uphill taxiway for example).

ON TAXIWAYS PLUS PAVED SHOULDERS LESS THAN 180 FT WIDE BUT MORE THAN 120 FT WIDE

- **If the surface beyond the paved area is free of loose objects at least until 180 ft wide (i.e. good grass, treated grass) :**
  The flight crew may use any of the engines if additional thrust is needed (uphill taxiway for example).
- **If the surface beyond the paved area contain loose objects (i.e. loose gravels or stones) :**
  The flight crew should prefer the use of the inner engines if additional thrust is needed (uphill taxiway for example).
  L2 Applying additional thrust on the outer engines may cause foreign object contamination of the taxiway pavement behind the aircraft, due to the jet blast of the engines.

L1 **ON TAXIWAY PLUS PAVED SHOULDERS LESS THAN 120 FT WIDE OR ON CONTAMINATED TAXIWAYS**

On taxiways plus paved shoulders less than 120 ft wide or if the taxiway pavement is contaminated, both the inner and the outer engines are above non-stabilized surface. In this configuration, the flight crew should prefer the use of the outer engines, if additional thrust is needed (uphill taxiway for example).

L2 The flight crew should maintain the inner engines at idle thrust in order to prevent the engines from ingesting foreign objects. The outer engines are high enough to prevent the risk of ingesting foreign objects at taxi thrust. However, the flight crew should apply any additional thrust on the outer engines, as smoothly as possible. The smooth application thrust limits the risk of foreign object contamination of the taxiway pavement behind the aircraft due to jet blast of the engines.

GENERAL

Applicable to: ALL

GENERAL ASPECTS

The flight crew must consider the two-engine taxi procedure in engine symmetrical configuration (engines 2+3 or 1+4).
Unless in some operational conditions (e.g. uphill slopes, high gross weight, tight turns), flight crew may consider to taxi only on two engines.
When taxiing on only two engines, the thrust per engine is higher than during a standard four-engine taxi. Therefore jet blast and the risk of Foreign Object Damage (FOD) by engine ingestion are higher.

L2 The use of either outer or inner engines for taxiing has no impact on hydraulic or electrical systems.

L1 TAXI ON ENGINES 2+3 OR 1+4 CONFIGURATION

RULES:

If the inner engines are above non stabilized surface (sand, loose gravels, snow), the flight crew should taxi on the outer engines (1+4).

L2 The inner engine air intakes are about 3 ft 5 in high above the ground at MTOW. The risks of FOD under the inner engines is significant in the case of non stabilized surface below the inner engines. For information, the outer engine air intakes are about 6 ft 3 in above the ground. For the outer engines and for usual taxi thrust, the risk of FOD by engine ingestion is remote.

L1 If a tight turn is expected during the taxi phase, the flight crew should consider the use of the outer engines (1+4), in order to take benefit of a greater momentum.

AT DEPARTURE

Applicable to: ALL

The flight crew should use the following procedures to taxi out, if company policy and regulations permit.
The SOP flow can be performed with only two symmetrical engine running.

TAXI ON OUTER ENGINES ONLY

ENGINE 1 and 4.....START
AFTER START SOP.....PERFORM

For a detailed description of the after start SOP , Refer to PRO-NOR-SOP-90-90 After start_ENG START selector .

AFTER START C/L.....DELAY

Delay the AFTER START checklist until all engines are started.

L2 Note: *The flight crew can perform the flight control check with only two symmetrical engines running.*

L1 TAXI SOP.....PERFORM

For a detailed description of the taxi SOP , Refer to PRO-NOR-SOP-100-100 Taxi_ CLEARANCE

ENGINE 2 and 3.....START

CAUTION	Start engines 2 and 3 at least 5 minutes before takeoff.

L2 Note: *5 min engine warm-up are necessary before applying high thrust.*

L1 AFTER START C/L.....PERFORM
BEFORE TAKEOFF SOP.....PERFORM

For a detailed description of the before takeoff SOP , Refer to PRO-NOR-SOP-110-110 Before takeoff_TAKEOFF OR LINE UP CLEARANCE .

TAXI ON INNER ENGINES ONLY

ENGINE 2 and 3.....START
AFTER START SOP.....PERFORM

For a detailed description of the after start SOP , Refer to PRO-NOR-SOP-90-90 After start_ENG START selector .

AFTER START C/L.....DELAY

Delay the AFTER START checklist until all engines are started.

L2 Note: *The flight crew can perform the flight control check with only two symmetrical engines running.*

L1 TAXI SOP.....PERFORM

For a detailed description of the taxi SOP , Refer to PRO-NOR-SOP-100-100 Taxi_ CLEARANCE

ENGINE 1 and 4.....START

CAUTION	Start engines 1 and 4 at least 5 minutes before takeoff.

L2 Note: *5 min engine warm-up are necessary before applying high thrust.*

L1 AFTER START C/L.....PERFORM
BEFORE TAKEOFF SOP.....PERFORM

For a detailed description of the before takeoff SOP , Refer to PRO-NOR-SOP-110-110 Before takeoff_TAKEOFF OR LINE UP CLEARANCE .

AT ARRIVAL

Applicable to: ALL

TAXI ON OUTER ENGINE ONLY

The flight crew should use the following procedure for taxi in:

CAUTION	Wait 3 min before shutting down the engines.

L2 *Note: For the inner engines, the use of reversers is considered as engine high thrust operation. 3 minutes are necessary for engine cooling before the flight crew shuts down the engines.*

L1 ENGINES 2 and 3.....SHUT DOWN

TAXI ON INNER ENGINE ONLY

The flight crew should use the following procedure for taxi in:

CAUTION	Wait 3 min before shuting down the engines.

L2 *Note: For the outer engines, the approach phase is considered as engine high thrust operation due to the possible thrust increase above idle during the approach. The outer engines are considered at low thrust only when the aircraft is on the ground. 3 minutes are necessary for engine cooling before the flight crew shuts down the engines.*

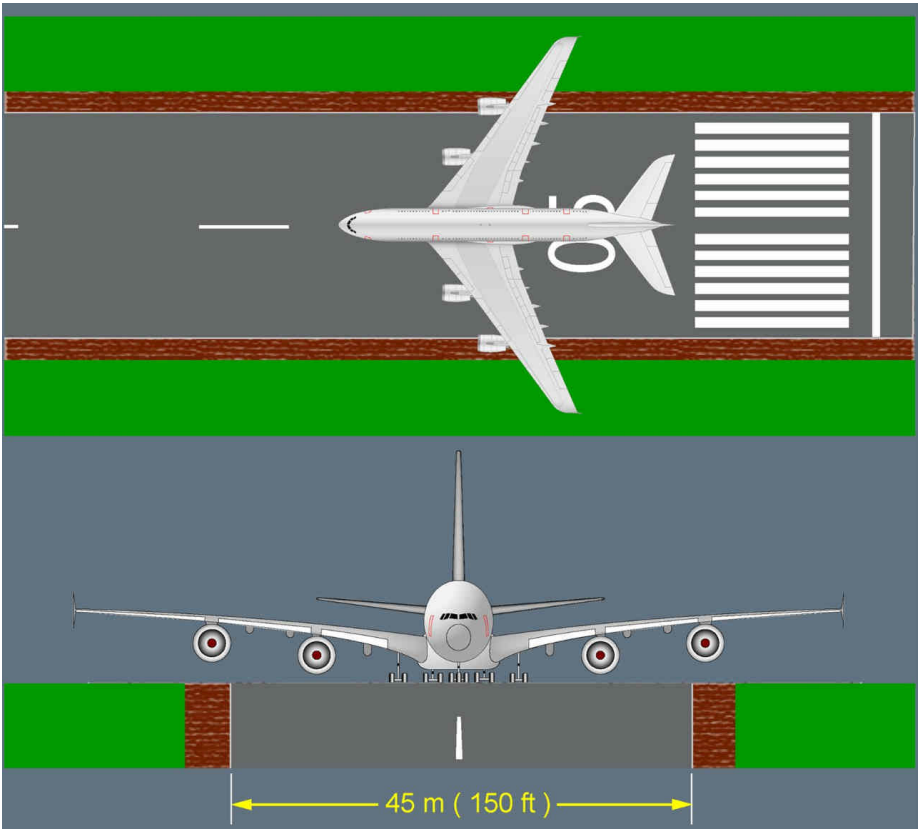
L1 ENGINES 1 and 4.....SHUT DOWN

Intentionally left blank

OPERATIONS ON RUNWAY + SHOULDERS LESS THAN 58 M (190 FT) WIDE

Applicable to: ALL

The minimum runway width for A380 takeoff and landing is 45 m (150 ft).
On a 45 m (150 ft) wide runway, the outer engines may be above non-stabilized surface depending on the width of the runway stabilized shoulders.
The following supplementary procedure only applies when the overall width of the runway plus stabilized shoulders is between 45 m (150 ft) and 58 m (190 ft).
The stabilized shoulders may be in asphalt or in grass (i.e. without loose gravels).
The natural soil beyond the stabilized surface of the runway may be non-stabilized (i.e. sand, loose gravels, snow).



This procedure limits the risk of contamination of the runway pavement behind the aircraft due to jet blast.

The standard operating procedures (*Refer to PRO-NOR-SOP-120-120 Takeoff_GENERAL*) remain applicable for operations on runway plus shoulders less than 58 m (190 ft) wide. In addition, apply the following procedure :

THRUST SETTING

TAKEOFF..... ANNOUNCE | PF
THR.....25% | PF

L2 *Apply 25% THR on all four engines with brakes on. However, the flight crew can release the brakes to perform a rolling takeoff.*

L1

- **If the crosswind is at, or below 23 kt , and there is no tailwind:**

  BRAKES.....RELEASE | PF
  THRUST LEVERS ON INNER ENGINES ONLY.....FLX or TOGA | PF

- **If the crosswind is above 23 kt , and/or in the case of tailwind:**

  BRAKES.....RELEASE | PF
  THRUST LEVERS ON INNER ENGINES ONLY..... 50% | PF

  - **At 20 kt ground speed:**

    THRUST LEVERS ON INNER ENGINES ONLY..... FLX or TOGA | PF

- **AT 40 kt :**

  THRUST LEVERS ON OUTER ENGINES.....FLX or TOGA | PF

DIRECTIONAL CONTROL..... USE RUDDER | PF
CHRONO.....START | PM
PFD/ND..... SCAN | PM
TAKEOFF THRUST..... CHECK | PM

L2 *Check that the current THR of each engine reached the THR rating limit value, before the aircraft reaches 80 kt .*

L1 Continue the takeoff procedure, as usual.

The application of the takeoff thrust setting procedure on a runway plus shoulders less than 58 m (190 ft) wide , has an impact on the takeoff distance. For more information on performance impact, *Refer to PER-TOF-TOC-RWY Operations on Runway + Shoulders less than 58 m Wide* .
The flight crew should check that the runway plus shoulders state is correctly defined in the takeoff performance application.

BRAKE COOLING TIME

Applicable to: ALL

CONTEXT

Based on the flight test campaign and on the brakes temperature observed on in service aircraft, a table is provided to estimate the brake cooling time.

This table enables the flight crew to predict the brake cooling time, taking into account:
- The current brake temperature displayed on the WHEEL SD page.
- The outside temperature displayed on the permanent data of the SD page (SAT).

SCOPE

The flight crew uses the brake cooling time table to estimate a minimum turnaround time based on the brake temperature.
At the gate, when the aircraft is stopped for at least for 15 min, the flight crew reads the maximum brake temperature displayed on the WHEEL SD page.

L2 For a better estimation of the turn around time, the flight crew should wait 15 min. Between the stop of the aircraft at the gate and 15 min later, the energy absorbed by the brakes during the taxi phase continues to impact the brake temperature behavior (I.e. increases the brake temperature or slows down the brake cooling).

L1 ESTIMATED BRAKE COOLING TIME TABLE IN MIN.

Current Hottest Brake Temp		300 °C	350 °C	400 °C	450 °C	500 °C	550 °C	600 °C	650 °C	700 °C
Temp. Target	SAT									
300 °C	-54 °C	0	16	29	42	53	63	72	81	89
	15 °C	0	19	35	50	63	74	85	94	103
	55 °C	0	22	40	56	70	83	94	104	114
250 °C	-54 °C	18	33	47	59	71	81	90	99	107
	15 °C	23	42	58	72	85	97	107	117	126
	55 °C	27	49	67	83	97	110	121	131	141
200 °C	-54 °C	39	55	68	81	92	102	111	120	128
	15 °C	51	70	86	101	113	125	135	145	154
	55 °C	62	84	102	118	132	144	156	166	176
150 °C	-54 °C	65	80	94	106	118	128	137	146	154
	15 °C	88	107	123	138	150	162	173	182	191
	55 °C	111	133	152	168	182	194	206	216	225

The flight crew enters the table with the current brake temperature at the top of the table. Function of the SAT, and the brake temperature target at the end of the cooling, the flight crew reads the estimated brake cooling time at the intersection of the line and the column.

L2 *Note:* *Example:*

- *SAT= 15 °C*
- *Current maximum brake temperature red on the WHEEL SD page= 550 °C*

The flight crew estimates the brake cooling time for a target brake temperature of 200 °C.

They read the value at the intersection of:

- *The 550 °C actual temperature column*
- *The line associated with 200 °C temperature target and a 15 °C SAT.*

125 min is the estimated time corresponding to the brake cooling time for the condition of the day.

L1 For intermediate values, the flight crew interpolates linearly.
The brake cooling time does not take into account the effect of the wind.
To increase the precision of the estimated brake cooling time, the flight crew can use the table several times during the brake cooling, taking the hottest brake temperature as a reference.

OVERVIEW

Applicable to: ALL

The Precision Runway Monitor (PRM) system enables simultaneous close parallel ILS approaches. The air traffic controllers use the PRM system to monitor the aircraft position. If necessary, the ATC orders a break out, turn and climb or descent.

To perform PRM operations:
- The air traffic controllers and the flight crews must fulfil specific training requirements
- The ATC and the aircraft equipment must fulfil specific requirements.

BREAK OUT TURN AND CLIMB PROCEDURE

Applicable to: ALL

Simultaneously:

AP..... OFF | PF
BREAK OUT LEFT(RIGHT), HDG___, ALT___..... ANNOUNCE | PF
THR LEVERS.....TOGA, and back to CL | PF

L2 *The SRS GA and the GA TRK modes engage. The THR CLB mode engages.*
The speed is managed. The speed target is the aircraft speed at SRS GA engagement.
The FMS GO-AROUND phase becomes active. Thus, the FMS reinserts the approach.

L1 TURN LEFT(RIGHT) AND CLIMB

L2 *As the situation is urgent, the flight crew should temporarily not follow the FD orders.*

L1 HDG___.....TURN AND PULL | PM

L2 *The GA TRK mode disengages, and the HDG mode engages.*

L1 ALT___..... TURN AND PULL | PM

L2 *The SRS GA mode disengages, and the OP CLB mode engages. The speed target becomes the FMS speed target of the CLIMB phase.*

L1 SPEED..... ADJUST | PM

L2 *For the initial break out procedure, adjust the speed (e.g. 160 kt), in order to avoid an important acceleration, and an increase of workload.*

L1 ● **When established on the break out path:**
AP.....ENGAGE | PM

L2 *Before engaging the AP, ensure that the FD bar orders approximately correspond to the aircraft current path.*

L1 SPEED.....SELECT AS RQRD | PF
FLAPS.....AS RQRD | PM
GEAR.....AS RQRD | PM

TCAS MODE SEL..... TA/RA AS RQRD | PM

BREAK OUT TURN AND DESCENT PROCEDURE

Applicable to: ALL

Simultaneously:

AP..... OFF | PF

TURN LEFT(RIGHT) AND MAINTAIN RATE OF DESCENT

BREAK OUT LEFT(RIGHT), HDG___, ALT___..... ANNOUNCE | PF

L2 *As the situation is urgent, the flight crew should temporarily not follow the FD orders.*

L1 HDG___.....TURN AND PULL | PM

L2 *The HDG mode engages. The vertical mode reverts to the V/S mode. The vertical speed target is the aircraft vertical speed at V/S engagement.*

L1 ALT___..... TURN AND PULL | PM

L2 *This action defines an altitude target. The OP DES mode and the THR IDLE mode engage. The speed target does not change.*

L1 V/S.....MONITOR | PM

CAUTION	*Depending on the speed target, the vertical speed may become excessive. If the rate of descent exceeds 1 000 ft/min, engage the V/S mode and limit the rate of descent to 1 000 ft/min.*

- **When established on the break out path:**

AP.....ENGAGE | PM

L2 *Before engaging the AP, ensure that the FD bar orders approximately correspond to the aircraft current path.*

L1

- **When cleared by ATC:**

ALT___..... TURN | PF

L2 *Select an altitude target for go-around, in accordance with the ATC clearance.*

L1 THR LEVERS..... TOGA, and back to CL | PF

L2 *The SRS GA and the GA TRK modes engage. The THR CLB mode engages.*
The speed is managed. The speed target is the aircraft speed at SRS GA engagement.
The FMS GO-AROUND phase becomes active.

L1 HDG___.....PULL | PF

L2 *The GA TRK mode disengages, and the HDG mode engages. The SRS GA mode remains engaged, until ALT* engagement.*

L1 SPEED.....SELECT AS RQRD | PF

FLAPS.....AS RQRD | PM

GEAR.....AS RQRD	PM
TCAS MODE SEL..... TA/RA AS RQRD	PM

Intentionally left blank

RULES FOR COMPUTER RESET

Applicable to: ALL

Some systems that operate abnormally, or that are detected failed by the ECAM , can be recovered by a computer reset.
The flight crew can perform a computer reset by using the cockpit controls (e.g. pushbuttons), or the reset buttons.

The flight crew must only attempt a computer reset when:
- It is requested by the ECAM procedure, or
- The flight crew detects or suspects a system failure and the associated computer reset is authorized by one of the listed procedures (*Refer to List of Computer Reset Procedures*)

The reset procedures give the conditions to perform a reset and also describes the precautions to take and the effects of the reset.

Unless indicated differently in the reset procedure, to perform a system reset:
- Set the normal control to OFF, or pull the reset button
- Wait three seconds if a normal cockpit control is used, or one second if a reset button was pulled
- Set the normal control to ON, or push the reset button.

The number of computer reset attempt is not limited.

WARNING	Several resets must not be performed at the same time, unless indicated in the applicable reset procedure.

Note: *In flight, before taking any action on the reset buttons, the PF and PM must:*
- *Consider and fully understand the consequences of taking action*
- *Crosscheck and verify that the reset button corresponds to the affected system.*

LIST OF COMPUTER RESET PROCEDURES

Applicable to: ALL

AESU 1(2) Reset (*Refer to reset procedure*)

AICU 1(2) Reset (*Refer to reset procedure*)

ARPT NAV Reset (*Refer to reset procedure*)

ATC Reset (*Refer to reset procedure*)

AVS 1(2) Reset (*Refer to reset procedure*)

BCSC 1(2) Reset (*Refer to reset procedure*)

CDLS Reset (*Refer to reset procedure*)

CIDS 1(2)(3) Reset (*Refer to reset procedure*)

CPCS 1(2) Reset (*Refer to reset procedure*)

ENG 1(2)(3)(4) EIPM 1(2) Reset (*Refer to reset procedure*)

FCU Reset (*Refer to reset procedure*)

FLAPS 1(2) Reset (*Refer to reset procedure*)

FMC A(B)(C) Reset (*Refer to reset procedure*)

FWS 1(2) Reset (*Refer to reset procedure*)

HUD Reset (*Refer to reset proccedure*)

NSS FLT OPS Reset (*Refer to reset procedure*)

PACK 1(2) CTL Reset (*Refer to reset procedure*)

SCS 1(2) Reset (*Refer to reset procedure*)

SDF 1(2)(3) Reset (*Refer to reset procedure*)

SLATS 1(2) Reset (*Refer to reset procedure*)

TCS 1(2) Reset (*Refer to reset procedure*)

TR 1(2) (ESS) Reset (*Refer to reset procedure*)

VCS 1(2) Reset (*Refer to reset procedure*)

PACK 1(2) CTL RESET

Applicable to: ALL

PACK 1 CTL Reset Button Location

PACK 2 CTL Reset Button Location

Before resetting one pack controller, ensure that the associated pack is off.
Do not reset both pack controllers at the same time.

TEMPERATURE CONTROL SYSTEM (TCS) 1(2) RESET

Applicable to: ALL

TCS 1(2) Reset Button Location

Do not reset both Temperature Control Systems at the same time.

Intentionally left blank

AVIONICS VENTILATION SYSTEM (AVS) 1(2) RESET

Applicable to: ALL

AVS 1 Reset Button Location

AVS 2 Reset Button Location

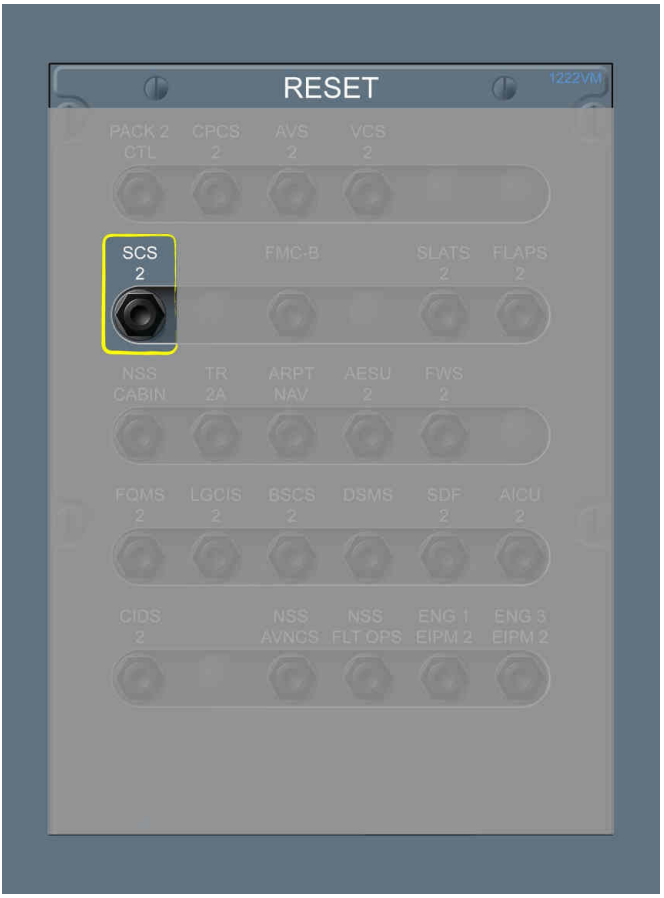
Reset both Avionics Ventilation Systems at the same time.

SUPPLEMENTAL COOLING SYSTEM (SCS) 1(2) RESET

Applicable to: ALL

SCS 1 Reset Button Location

SCS 2 Reset Button Location



The cabin crew will inform the flight crew, when a reset of the Supplemental Cooling System (SCS) should be performed.

COOLG PB SW.....OFF
SCS 1 and SCS 2 RESETs..... PULL

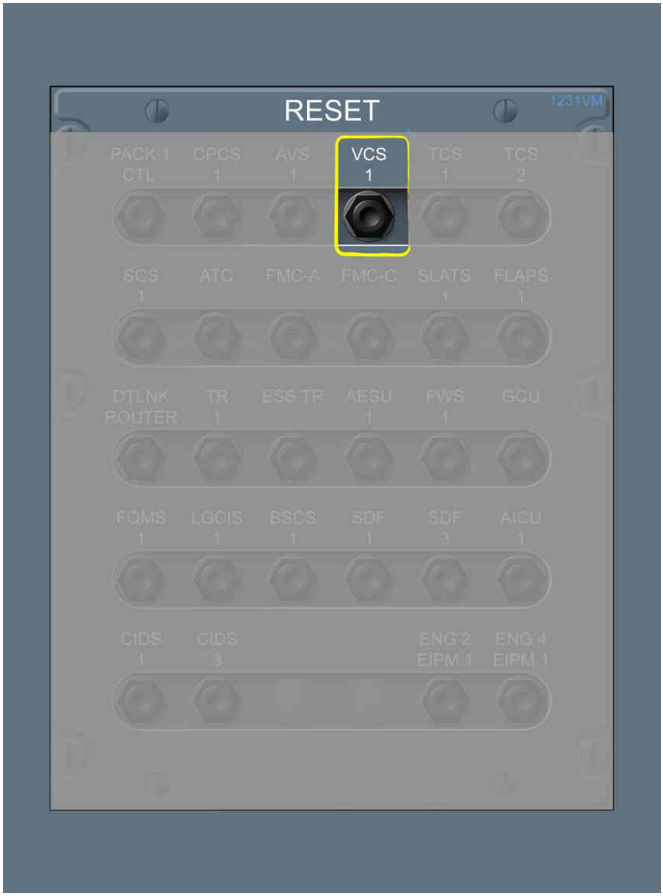
- **After 5 s:**
  SCS 1 and SCS 2 RESETs.....PUSH
- **After 2 s:**
  COOLG PB SW.....AUTO

Note: *If the reset of the SCS is not successful, this indicates that the failure is latched for the remainder of the flight. Any other reset attempts will have no effect.*

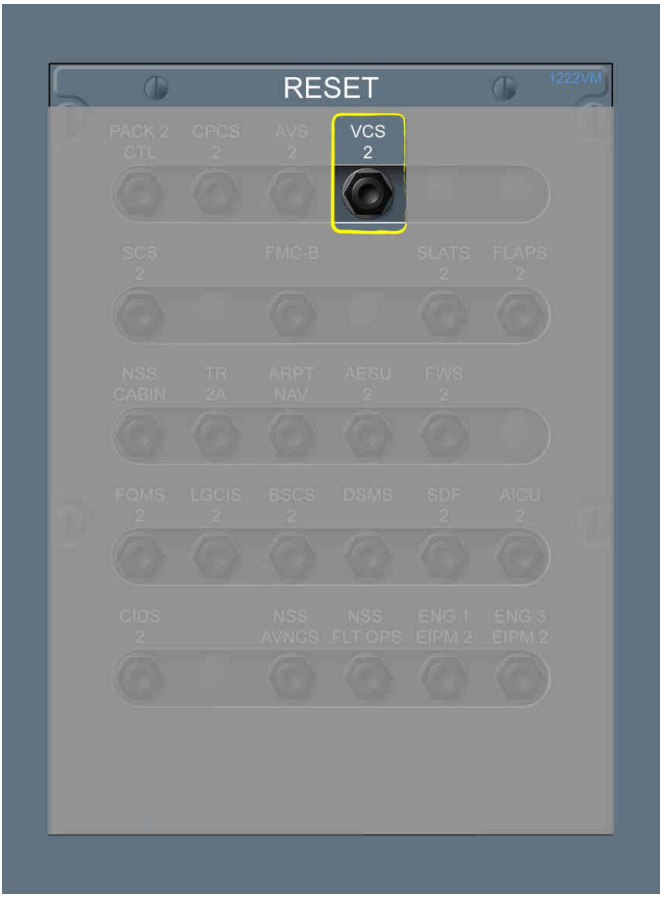
VENTILATION CONTROL SYSTEM (VCS) 1(2) RESET

Applicable to: ALL

VCS 1 Reset Button Location



VCS 2 Reset Button Location



In the case of a smoke warning in the lower Cabin Crew Rest Compartment (CCRC), the ventilation of this compartment automatically stops. In flight, in the case of an erroneous smoke warning, the flight crew can perform a reset of the Ventilation Control System (VCS) to recover the ventilation in the CCRC.

CAUTION	Do not reset the VCS in the case of smoke warning affecting a cargo compartment, or if the cabin crew cannot visually confirm the absence of smoke or smoke source in the CCRC

VCS 1 RESET..... PULL

- **After 5 s:**

VCS 1 RESET.....PUSH

VCS 2 RESET..... PULL

- **After 5 s:**

VCS 2 RESET.....PUSH

Note: *In flight, the flight crew should not reset both Ventilation Control Systems (VCS) at the same time, to avoid the loss of the In-Flight Entertainment, and a reduced airflow in the cabin during the reset.*

Intentionally left blank

CABIN PRESSURE CONTROL SYSTEM (CPCS) 1(2) RESET

Applicable to: ALL

CPCS 1 Reset Button Location

CPCS 2 Reset Button Location

It is possible to perform a reset of the CPCS 1(2) reset buttons, when the automatic mode of the Cabin Pressure Control System does not operate normally (e.g. outflow valve oscillations associated with high cabin rates).

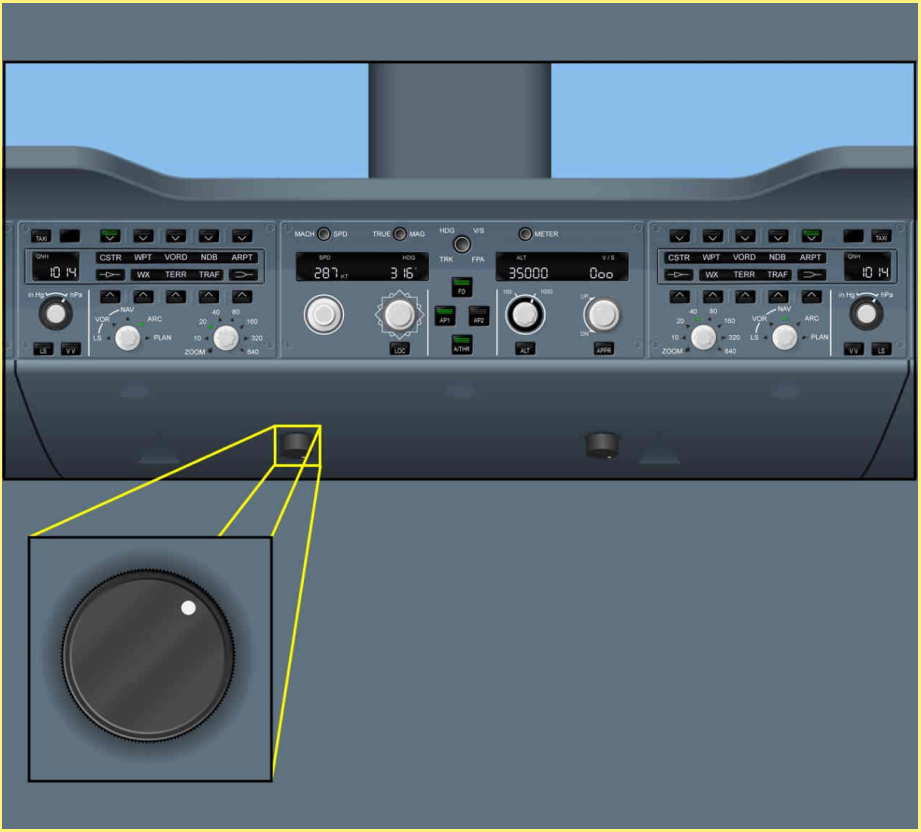
CPCS 1 then CPCS 2 RESETs..... PULL

- **After 1 s:**
  CPCS 2 then CPCS 1 RESETs.....PUSH

FLIGHT CONTROL UNIT (FCU) RESET

Applicable to: ALL
Impacted DU: 00019430 Flight Control Unit (FCU) Reset

Left FCU Brightness Knob Location



It is possible to perform the following reset procedure, in the case of FCU failure.
In flight, do not perform a FCU reset, if the AFS CP only fails.

LEFT FCU BRIGHTNESS KNOB.....TURN OFF 3 s then ON

This action switches off, then on both EFIS CPs and the AFS CP.

FCU TARGETS AND SELECTIONS..... CHECK

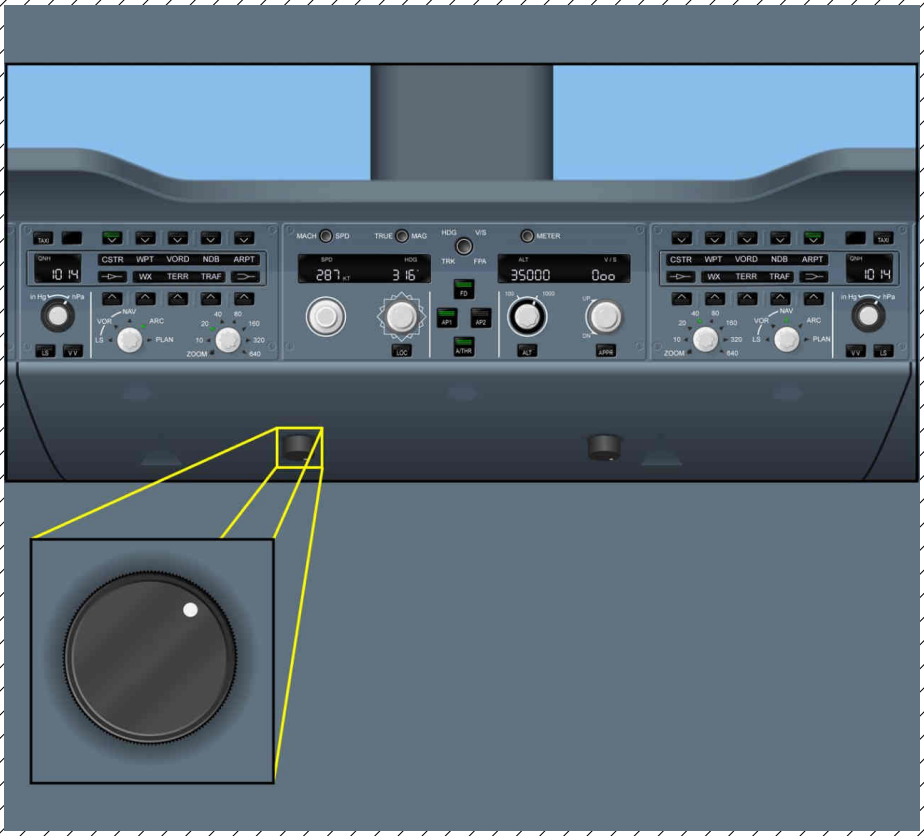
Check targets, and selections on the AFS CP and both EFIS CPs.

When on ground, with engines stopped, the barometric references (values and QNH/STD selection) on both EFIS CPs may be erroneous: In such a case, set the appropriate barometric references on both EFIS CPs.

FLIGHT CONTROL UNIT (FCU) RESET

Applicable to: ALL
Impacted by TDU: 00019639 Flight Control Unit (FCU) Reset

Left FCU Brightness Knob Location



It is possible to perform the following reset procedure, in the case of FCU failure.
In flight, do not perform a FCU reset, if the AFS CP only fails.

LEFT FCU BRIGHTNESS KNOB.....TURN OFF 3 s then ON

This action switches off, then on both EFIS CPs and the AFS CP.

FCU TARGETS AND SELECTIONS.....CHECK

Check targets, and selections on the AFS CP and both EFIS CPs.

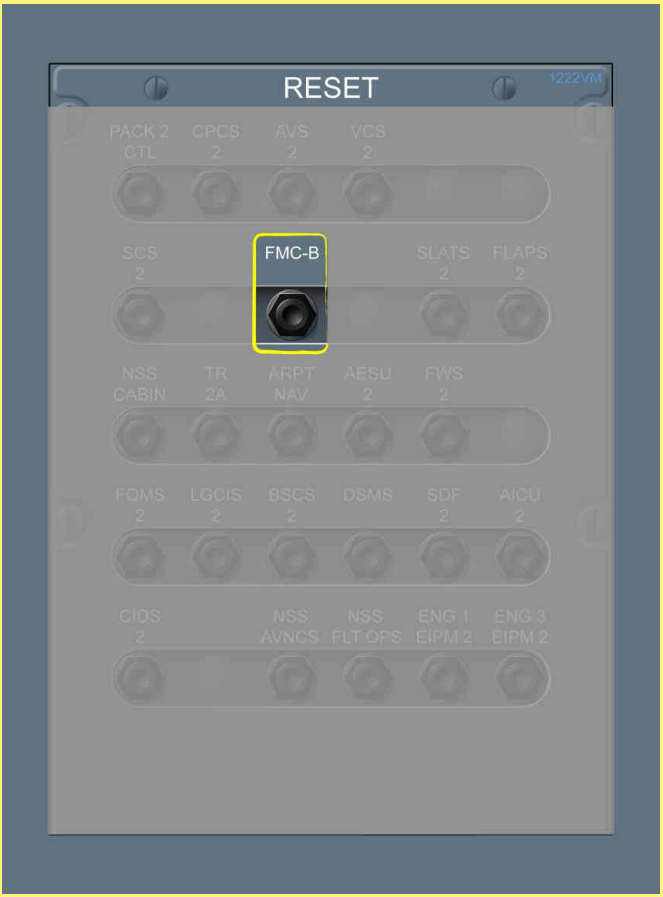
Intentionally left blank

FLIGHT MANAGEMENT COMPUTER FMC A(B)(C) RESET

Applicable to: ALL
Impacted DU: 00019415 Flight Management Computer FMC A(B)(C) Reset

FMC A(C) Reset Button Location

FMC B Reset Button Location



It is possible to perform a FMC A(B)(C) reset in the case of:
- A malfunction of the FMC (with or without the associated FMC A(B)(C) FAULT alert on the ECAM), or
- The three FMC s are not in the normal operation configuration.

Refer to Manual FMC Reset

● **In the case of a malfunction of an FMC :**
AFFECTED FMC RESET..... PULL

- **After 2 s :**
  AFFECTED FMC RESET..... PUSH

- **If the three FMC s are not in the normal operation configuration:**
  ONE FMC RESET IN ABNORMAL CONFIGURATION..... PULL

- **After 10 s :**
  AFFECTED FMC RESET..... PUSH

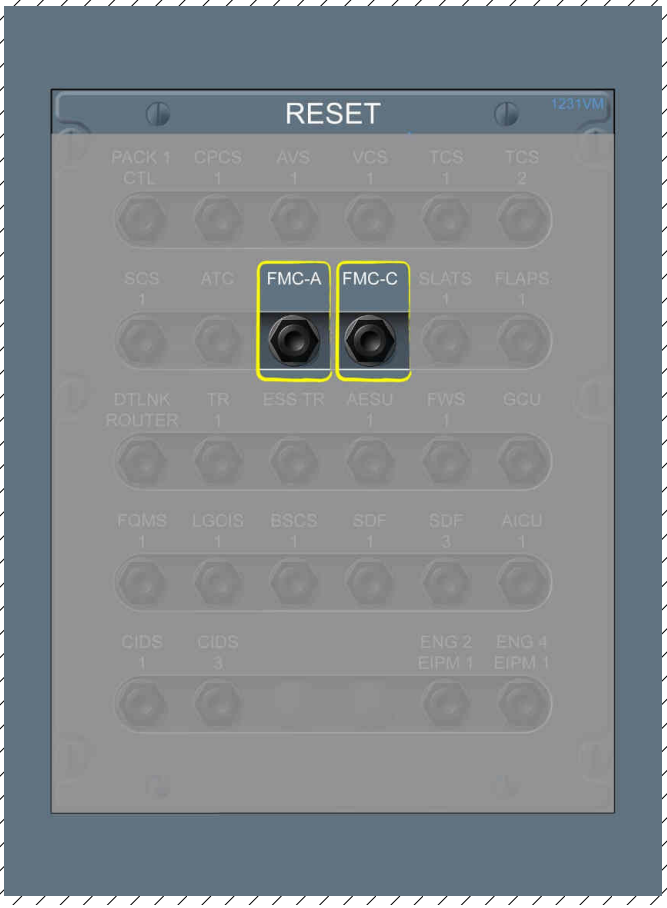
L2 *Note:* *After the FMS reset, the STATUS page may display CAT 2 as Inoperative System, with no associated alert. This may happen if the initial departure runway had no ILS . In this case only, to clear the CAT 2 INOP SYS message, the flight crew should perform the following actions:*

- *Select the POSITION / NAVAIDS page of the MFD*
- *Enter a valid ILS ident (e.g. ILS at destination)*
- *Check that the CAT 2 INOP SYS disappears on the STATUS page*
- *Clear the ILS ident on the POSITION / NAVAIDS page of the MFD .*

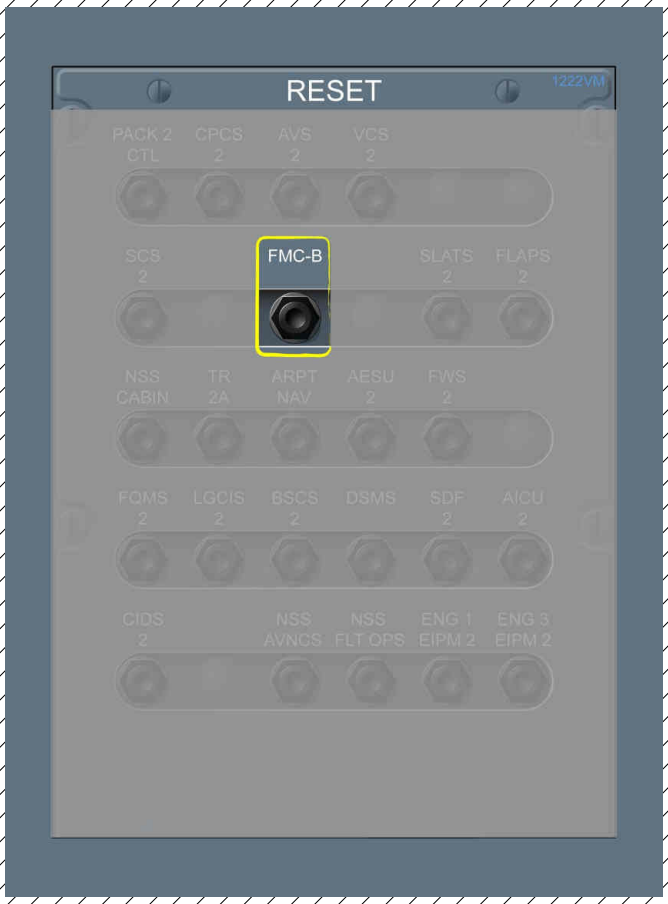
FLIGHT MANAGEMENT COMPUTER (FMC) A(B)(C)

Applicable to: ALL
Impacted by TDU: 00023890 Flight Management Computer FMC A(B)(C) Reset

FMC A(C) Reset Button Location



FMC B Reset Button Location



It is possible to perform a FMC A(B)(C) reset in the case of:
- A malfunction of the FMC (with or without the associated FMC A(B)(C) FAULT alert on the ECAM), or
- The three FMC s are not in the normal operation configuration.

Refer to Manual FMC Reset

● **In the case of a malfunction of an FMC :**
AFFECTED FMC RESET ..... PULL

- **After 2 s :**

  AFFECTED FMC RESET.....PUSH

- **If the three FMC s are not in the normal operation configuration:**

  ONE FMC RESET IN ABNORMAL CONFIGURATION.....PULL

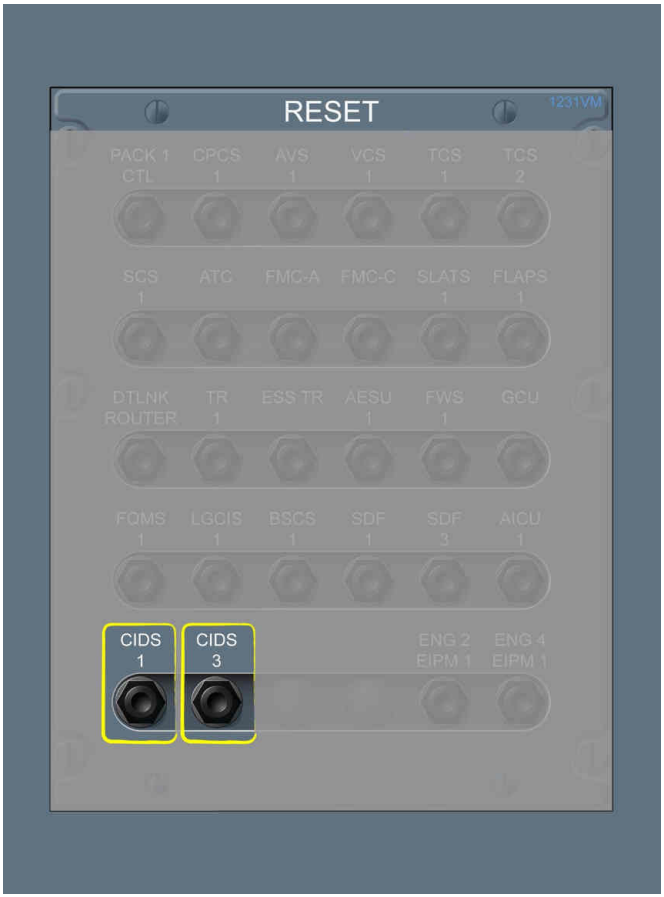
- **After 10 s :**

  AFFECTED FMC RESET.....PUSH

CABIN INTERCOMMUNICATION DATA SYSTEM (CIDS) 1(2)(3) RESET

Applicable to: ALL

CIDS 1(3) Reset Buttons Location



CIDS 2 Reset Buttons Location

The cabin crew informs the flight crew, when a reset of the CIDS should be performed.

- **When on ground, and no passengers on board:**
  - **If the cabin crew requests a CIDS reset:**

    Be aware that the CIDS reset will result in the loss of PA and interphone for 3 min.

    CIDS 3 RESET.....PULL

    - **After 5 s:**

      CIDS 2 RESET.....PULL

- **After 5 s:**
  CIDS 1 RESET.....PULL
  - **After 5 s:**
    CIDS 1, 2 AND 3 RESET.....PUSH AT THE SAME TIME

    This action leads to:
    - *Full bright cabin illumination*
    - *Loss of basic CIDS functions (e.g. PA, interphone) for 3 min*
    - *The FAPs and mini-FAPs are not available for 5 min.*

    The ECAM will trigger the CAB COM CIDS 1+2+3 FAULT alert.

    Disregard this alert.
    CABIN CREW.....ADVISE
    Inform the cabin crew that the cabin systems should be recovered in 5 min.

- **When on ground, with passengers on board, or when in flight:**
  - **If the cabin crew requests a CIDS reset:**
    CIDS 1 RESET.....PULL
    CABIN CREW.....ADVISE
    Inform the cabin crew that the cabin systems should be recovered in 1 min.
    - **After 1 min, if the cabin crew informs that the pull action on the CIDS 1 reset button is successful:**
      CIDS 1 RESET.....KEEP PULLED
    - **If the cabin crew informs that the pull action on the CIDS 1 reset button is not successful:**
      CIDS 1 RESET.....PUSH
      CIDS 1 restarts.

      If CIDS 1 succeeds to become the active computer, the following occurs:
      - *CIDS 1 takes into account default settings*
        These default settings lead to full bright cabin illumination.
      - *The basic CIDS functions (e.g. PA, interphone) are lost for 30 s*
      - *The FAPs and mini-FAPs are not available for 5 min.*

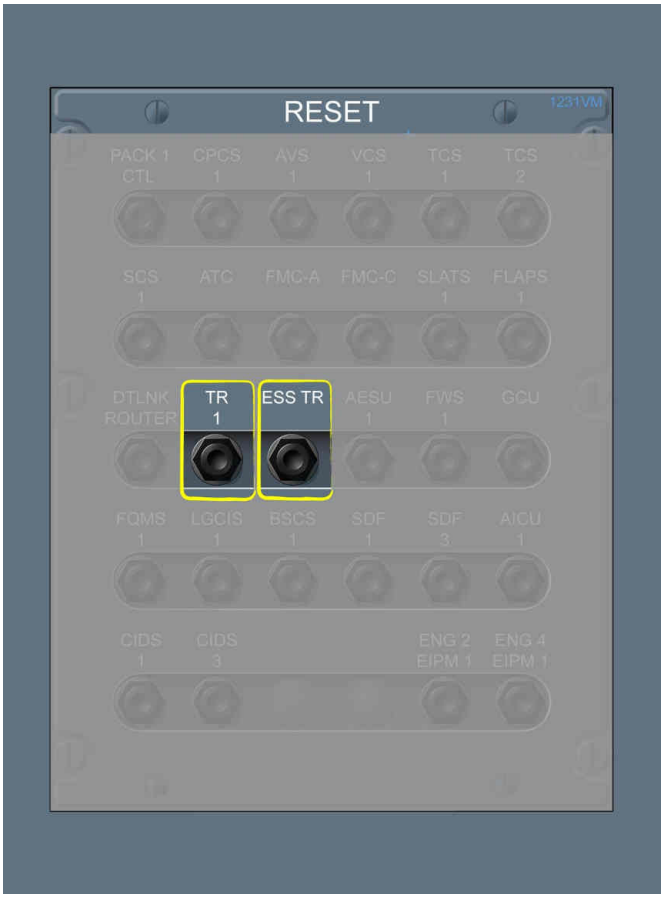
      If the push action is successful, the cabin systems are recovered after 5 min.
      CABIN CREW.....ADVISE
      Inform the cabin crew that the cabin systems should be recovered in 5 min.
      - **After 5 min, if the cabin crew informs that the push action on the CIDS 1 reset button is not successful:**
        Repeat the same actions on the CIDS 2 reset button.

After 5 min, if the cabin crew informs the flight crew that the push action on the CIDS 2 reset button is not successful, the flight crew should check that CIDS 1 and CIDS 2 reset buttons are pushed. Then, repeat the same actions on the CIDS 3 reset button.

TRANSFORMER RECTIFIER (TR) 1(2) (ESS) RESET

Applicable to: ALL

TR 1 and ESS TR Reset Button Location



TR 2 Reset Button Location

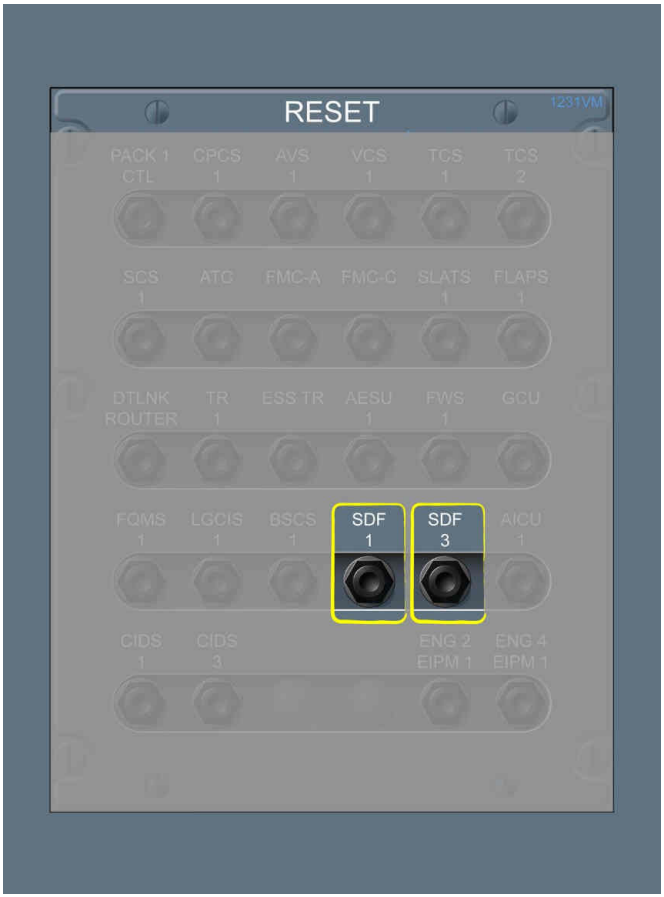
It is possible to perform a TR 1, TR 2, or ESS TR reset, on ground only.

Note: *Pull the TR 1(2)(ESS) reset button less than 5 s, to avoid latching the ELEC TR 1(2A)(ESS) FAULT alert.*

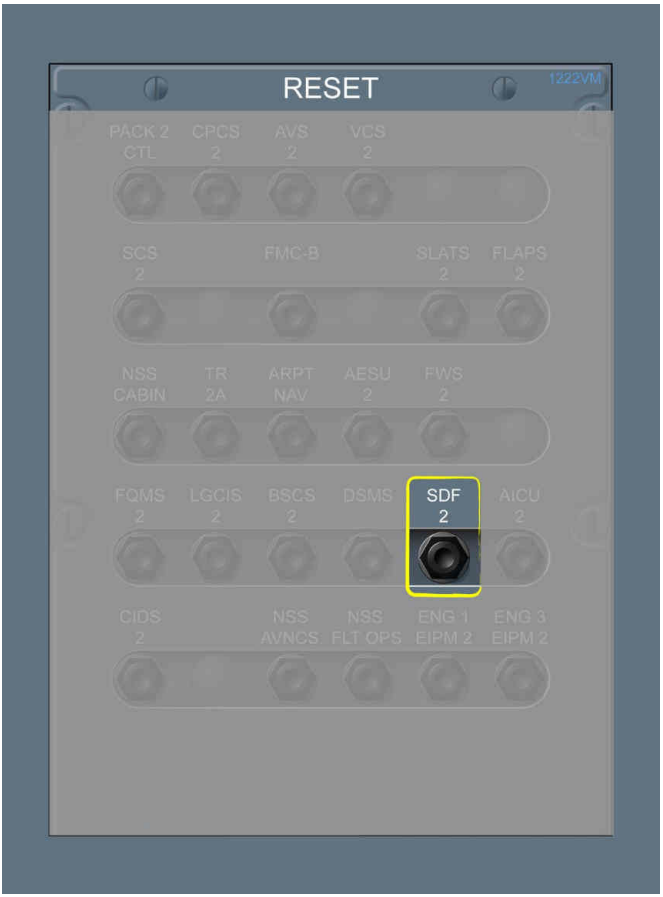
SMOKE DETECTION FUNCTION (SDF) 1(2)(3) RESET

Applicable to: ALL

SDF 1 and SDF 3 Reset Button Location



SDF 2 Reset Button Location



The flight crew can perform a reset of the SDF only if at least two of the following smoke detection fault alerts are triggered:

- SMOKE AFT AVNCS DET FAULT
- SMOKE L(R) MAIN(UPPER) AVNCS DET FAULT
- SMOKE IFE BAY DET FAULT
- SMOKE FWD(AFT/BULK) DET FAULT
- SMOKE AFT LWR CAB REST DET FAULT
- SMOKE UPPER 1R SOCIAL AREA DET FAULT

For the following smoke detection fault alerts, the flight crew can perform a CIDS reset (*Refer to PRO-SUP-24-23 Cabin Intercommunication Data System (CIDS) 1(2)(3) Reset*) instead of a SDF reset:

- SMOKE MAIN(UPPER) DECK LAVATORY DET FAULT
- SMOKE MAIN(UPPER) XX CWS DET FAULT

Note: Depending on the failure, the active CIDS computer can be CIDS 1, 2 or 3. When the flight crew pulls the SDF reset button associated with the active CIDS computer, the active CIDS computer changes. This can lead to disturbance in the cabin during few minutes (For more information on CIDS computer reset procedure, Refer to PRO-SUP-24-23 Cabin Intercommunication Data System (CIDS) 1(2)(3) Reset)

SDF 3 RESET..... PULL then PUSH after 4 s

- **After 20 s :**
  SDF 2 RESET..... PULL then PUSH after 4 s
- **After 20 s**
  SDF 1 RESET..... PULL then PUSH after 4 s

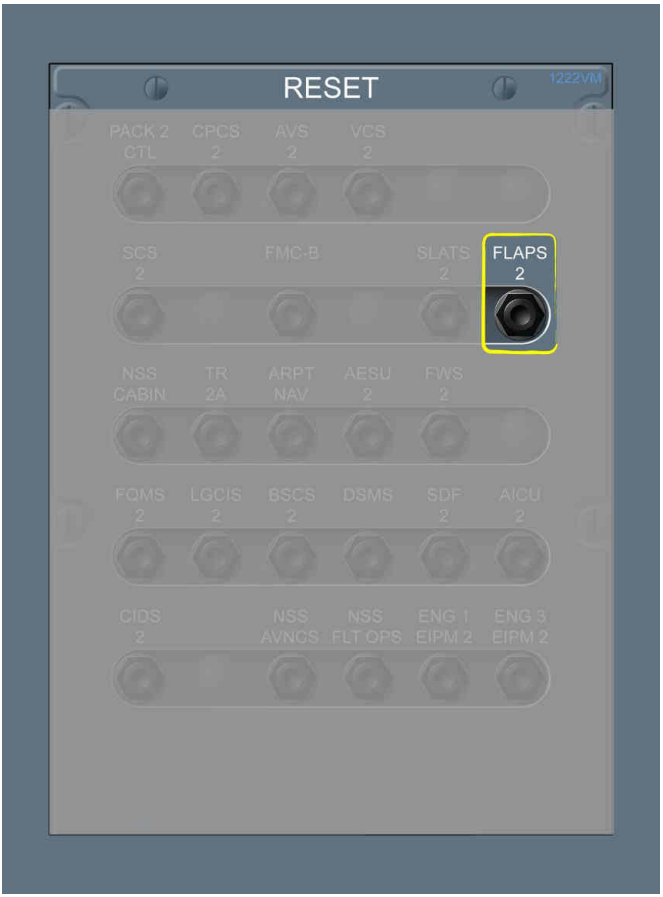
Intentionally left blank

FLAPS 1(2) RESET

Applicable to: ALL

FLAPS 1 Reset Button Location

FLAPS 2 Reset Button Location



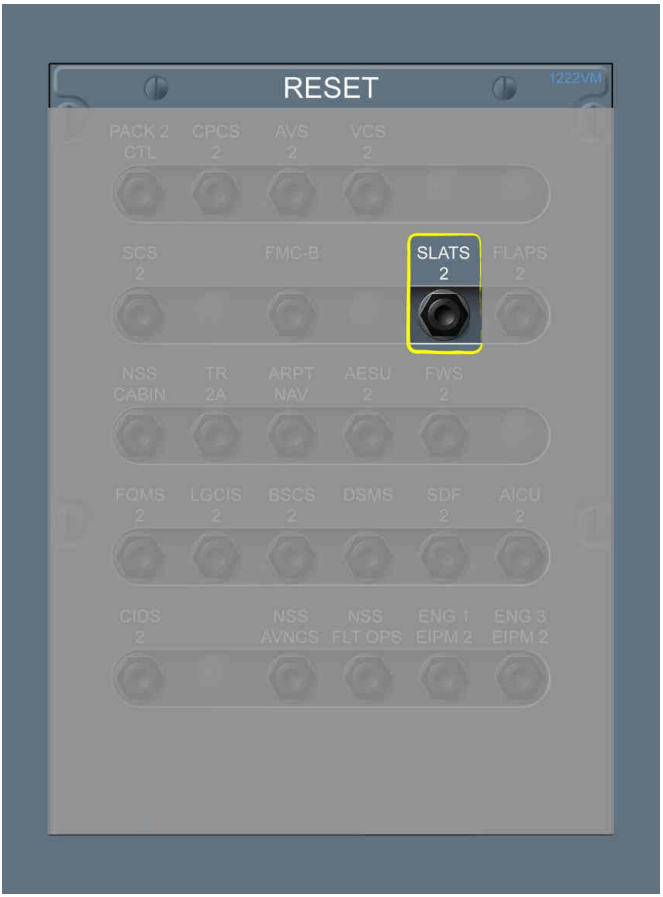
Do not perform any reset of the flaps control unit during flaps movement, and do not reset both flaps control units at the same time.

SLATS 1(2) RESET

Applicable to: ALL

SLATS 1 Reset Button Location

SLATS 2 Reset Button Location



Do not perform any reset of slats control unit reset during slats movement, and do not reset both slats control units at the same time.

ANTI ICE CONTROL UNIT (AICU) 1(2) RESET

Applicable to: ALL

AICU 1 Reset Button Location

AICU 2 Reset Button Location

AICU 1 then AICU 2 RESETs.....PULL

- **After 10 s:**
  AICU 1 and AICU 2 RESETs..... PUSH

Wait 30 s before using the wing and/or engine anti-ice.

FLIGHT CONTROL UNIT (FCU) RESET

Applicable to: ALL

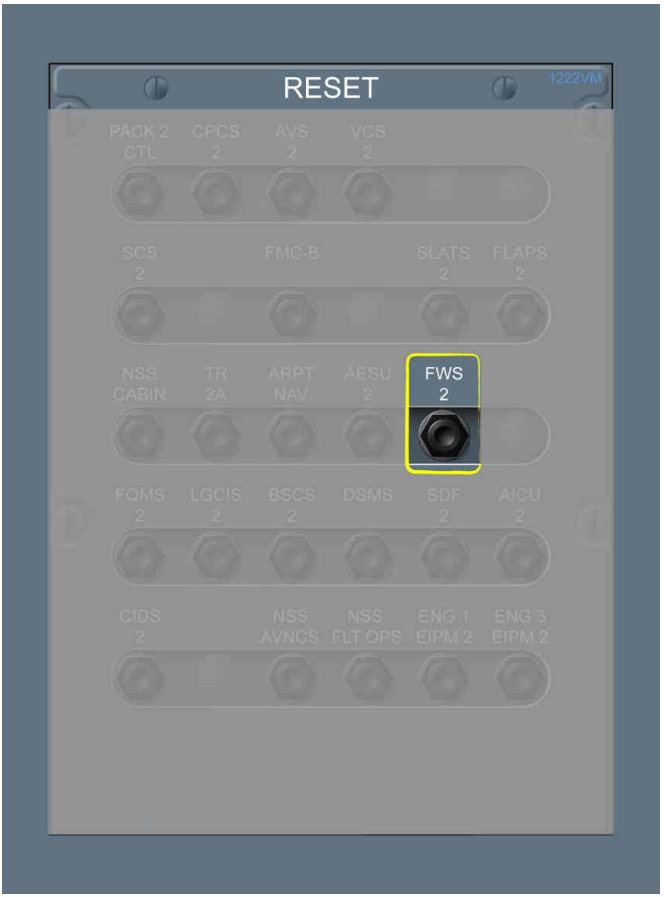
Refer to FCU reset procedure .

FLIGHT WARNING SYSTEM (FWS) 1(2) RESET

Applicable to: ALL

FWS 1 Reset Button Location

FWS 2 Reset Button Location



On ground, it is possible to perform the following reset procedure, when there is a malfunction of FWS 1 and/or FWS 2.
In flight, it is possible to perform the following reset procedure, only when there is a malfunction on both FWS 1 and FWS 2.

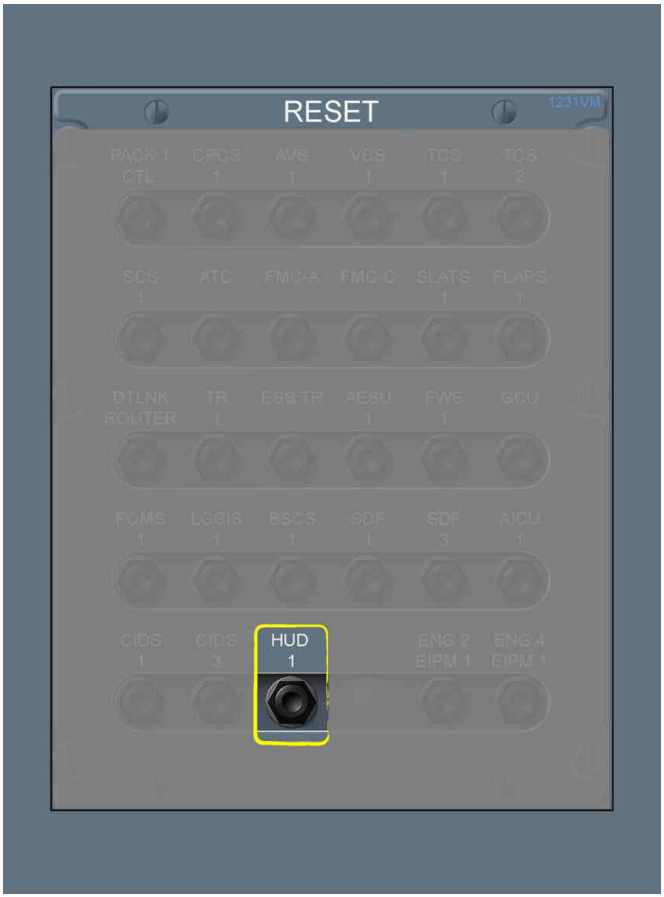
FWS 1 and FWS 2 RESETs .....PULL

- **When the CDS FWS 1+2 FAULT alert triggers:**
  FWS 2 RESET then FWS 1 RESET..... PUSH

HEAD-UP DISPLAY (HUD) RESET

Applicable to: ALL

HUD 1 Reset Button Location



In the case of HUD failure, wait for automatic HUD recovery during maximum 2 min.
It is possible to perform a HUD reset, if the HUD automatic reset is not successful.

HUD 1 RESET..... PULL

● **After 5 s:**

HUD 1 RESET..... PUSH

The HUD may display SELF TEST IN PROGRESS - MAX XX SEC for a few seconds before the HUD is recovered.

■ **If the HUD reset is successful:**

HUD USE.....AS RQRD

■ **If the HUD reset is not successful:**

Continue using the PFD and the ND.

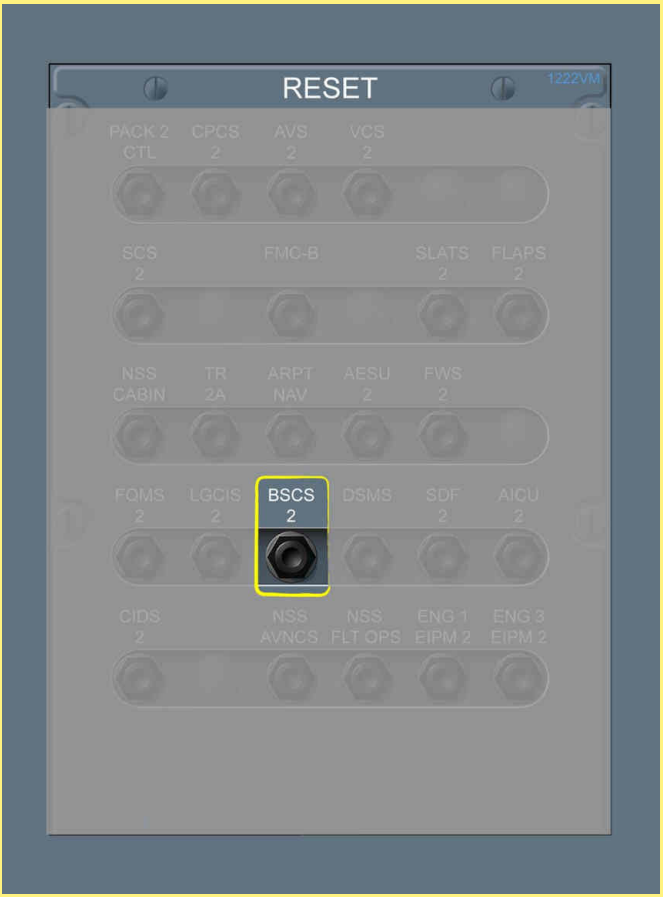
HUD..... STOW

BRAKE AND STEERING CONTROL SYSTEM (BSCS) 1(2) RESET

Applicable to: ALL
Impacted DU: NONE

BSCS 1 Reset Button Location

BSCS 2 Reset Button Location



ECAM ALERTS.....RECALL

Check any BRAKES or STEER alert (s) other than STEER B/W STEER NOT LOCKED.

- **If other BRAKES or STEER alerts are displayed:**

  The BSCS reset is not allowed

● **If no other BRAKES or STEER alert is displayed (STEER B/W STEER NOT LOCKED only):**

TAXI OR TOW THE A/C IN STRAIGHT LINE OVER 165 FT

L2 *Taxi or tow the aircraft in straight line over about 165 ft reduces Body Landing Gear stress and facilitates the locking of the BWS.*

L1 PARKING BRAKE.....ON
BSCS 1 RESET.....PULL
BSCS 1 RESET.....PUSH

● **When BSCS 1 reset:**
BSCS 2 RESET.....PULL
BSCS 2 RESET.....PUSH

PARKING BRAKE.....OFF

● **IF NOT SUCCESSFUL**
PARKING BRAKE.....ON
BSCS 2 RESET.....PULL
BSCS 2 RESET.....PUSH

● **When BSCS 2 reset:**
BSCS 1 RESET.....PULL
BSCS 1 RESET.....PUSH

PARKING BRAKE.....OFF

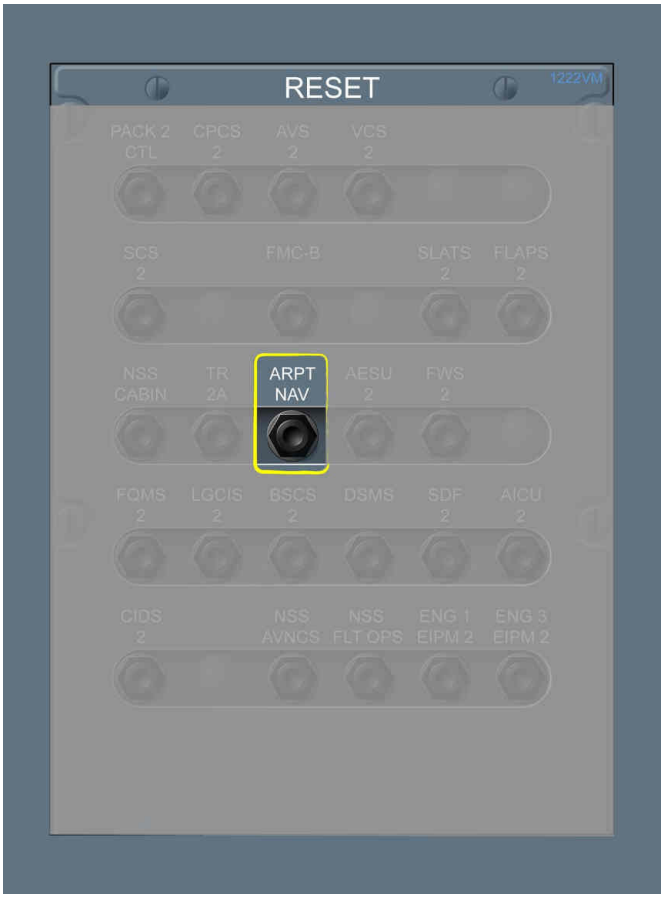
Note:
1. *If the BSCS 1 and BSCS 2 are reset simultaneously, the aircraft looses all steering capability and the braking degrades to EMERGENCY mode.*
2. *The BSCS will attempt to re-lock the BWS when the BSCS 1 and BSCS 2 are reset and the parking brake set to OFF.*
3. *If the STEER B/W STEER NOT LOCKED alert appears again after the release of the parking brake, dispatch is not allowed.*

Intentionally left blank

AIRPORT NAVIGATION (ARPT NAV) RESET

Applicable to: ALL

ARPT NAV Reset Button Location



ARPT NAV RESET.....PULL

- **After 10 s:**
  ARPT NAV RESET.....PUSH

Intentionally left blank

AIRCRAFT ENVIRONMENTAL SURVEILANCE UNIT (AESU) 1(2) RESET

Applicable to: ALL

AESU 1 Reset Button Location

AESU 2 Reset Button Location

It is possible to perform a reset of the AESU 1(2), when the surveillance system does not operate normally.

AESU 1 and AESU 2 RESETS.....PULL

- **When the SURV SYS 1+2 FAULT alert triggers:**
  AESU 1 then AESU 2 RESET.....PUSH

AIR TRAFFIC CONTROL (ATC) RESET

Applicable to: ALL

ATC Reset Button Location

It is possible to perform an ATC reset, when:

- MAILBOX NOT AVAIL is displayed on the lower part of the SD , or
- ATC COM PAGE NOT AVAIL is displayed on the CAPT and/or F/O MFD (s).

Note: *Inform by voice the ATC center that ADS will be set to OFF and that ATC will be reset (for appropriate phraseology, refer to regional procedures).*

ADS.....OFF

L2 *When possible, set the ADS OFF on the CONNECT/CONNECTION STATUS page (Refer to DSC-46-10-20-30-20 CONNECTION STATUS Page).*

Setting the ADS OFF :
- *Closes all current ADS connections*
- *Sends a disconnect message to all the connected ATC centers.*

L1 ATC RESET.....PULL

L2 *The alert COM ATC DATALINK FAULT may appear during the reset.*

L1 ● **After 1 s :**
ATC RESET..... PUSH

L2 *Following an ATC reset:*
- *All current CPDLC and ADS connections are lost*
- *Mailbox messages are lost*
- *All the messages stored in the MSG RECORD/LIST page are kept (Refer to DSC-46-10-20-30-80 MSG RECORD/LIST Page).*

L1 *Note: If the flight crew directly resets the ATC without setting the ADS OFF , no ADS disconnect message will be sent to the connected ATC centers. Therefore, ADS connections may not be properly closed and the ATC centers may have difficulties to establish again ADS connection with the aircraft after the notification.*

ATC CENTER.....NOTIFY

L2 *Notify the ATC center on the CONNECT/NOTIFICATION page (Refer to DSC-46-10-20-30-10 NOTIFICATION Page).*
The ATC center will establish again ADS and CPDLC connections.

NETWORK SERVER SYSTEM (NSS) FLIGHT OPERATIONS (FLT OPS) RESET

Applicable to: ALL

NSS FLT OPS Reset Button Location

It is possible to perform an NSS FLT OPS reset, when CAPT and F/O OITs do not display the FLT OPS side, and when CAPT and F/O laptops are operative.

CAPT & F/O LAPTOPS.....OFF

L2 *To turn off the laptops, slide the laptops ON/OFF sw to the right for no more than 2 s.*

L1 BOTH OIT BRIGHTNESS KNOB.....OFF

NSS FLT OPS RESET.....PULL

- **After 5 s:**

  NSS FLT OPS RESET.....PUSH

BOTH OIT BRIGHTNESS KNOB.....ON

- **After one minute:**

  CAPT & F/O LAPTOPS.....ON

L2 *To turn on the laptops, slide the laptops ON/OFF sw to the right for no more than 2 s.*

L1 L12

Note: The laptop takes approximately 5 min to restart.

COCKPIT DOOR LOCKING SYSTEM (CDLS) RESET

Applicable to: ALL

It is possible to perform a CDLS reset when at least one STRIKE light on the CKPT DOOR CONT overhead panel is amber.

CKPT DOOR CONT Panel

COCKPIT DOOR..... OPEN
CKPT DOOR SW..... UNLOCK 10 s

Maintain the CKPT DOOR sw in the UNLOCK position for 10 s to reset and to attempt to recover the CDLS:

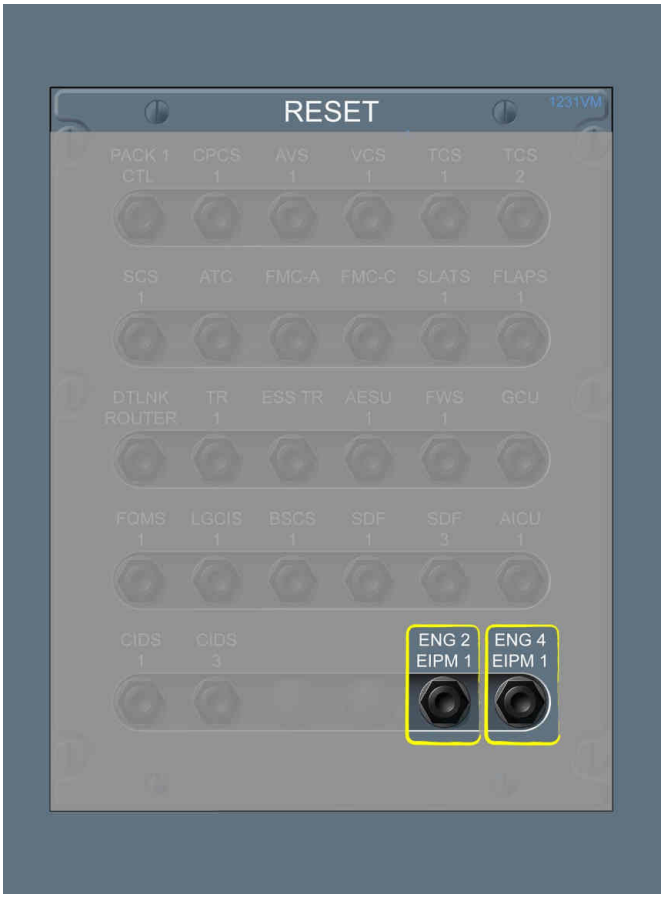
- *If the STRIKE light goes off, the system has resumed normal operation*
- *If the light remains on, the CDLS is failed.*

Intentionally left blank

ENG 1(2)(3)(4) ENGINE INTERFACE POWER MANAGEMENT (EIPM) 1(2) RESET

Applicable to: ALL

ENG 2(4) EIPM 1 Reset Button Location



ENG 1(3) EIPM 2 Reset

It is possible to perform a reset of the applicable engine EIPM, when the parameters of the associated engine on the ENG SD page are replaced by amber crosses.

OVERVIEW

Applicable to: ALL

Operations on fluid contaminated runways require the application of special procedures. These procedures are applicable to the following phases of flight:

- Taxi
- Takeoff
- Landing
- After Landing.

For the associated performance limitations to be applied during these phases of flight, refer to the AFM.

TAXI

Applicable to: ALL

TAXI SOP.....PERFORM

For a detailed description of the Taxi SOP, Refer to the associated procedure .

● **In addition, apply the following procedures:**

When taxiing on slippery surfaces, maintain the aircraft far behind the aircraft in front.

THRUST LEVERS..... AS RQRD

L2 *Avoid high thrust settings.*

L1 TAXI SPEED..... LOW

L2
- *Remember that the antiskid is inhibited at very low speeds.*
- *For turns with large nosewheel steering angles (minimum radius):*
  - *Noise and vibrations may be due to wheel skid*
  - *Maintain the speed as low as possible (max 5 kt), to prevent wheel skid and/or an increase in turn radius*
  - *If necessary, use the outer engine and differential braking. Maintain the other engines at idle*
  - *Do not apply symmetrical thrust to prevent wheel skid and/or an increase in turn radius.*
- *If the body wheel steering is inoperative:*
  - *Do not perform brake pivot turns to prevent wheel skid and/or an increase in turn radius*
  - *On slippery or contaminated runways, minimize the tiller angle.*

L1 ● **Icing conditions with rain, slush, or snow may contaminate the runways and taxiways:**

SLATS/FLAPS.....RETRACTED

L2 *Maintain the slats/flaps retracted, until the aircraft reaches the holding point on the takeoff runway, in order to prevent contamination of the slats/flaps mechanism.*

L1 BEFORE TAKEOFF CHECKLIST.....KEEP ON HOLD

L2 *Stop the BEFORE TAKEOFF checklist before the FLAPS T.O setting. After slats/flaps extension, continue and complete the BEFORE TAKEOFF checklist.*

TAKEOFF

Applicable to: ALL

TAKEOFF SOP.....PERFORM

For a detailed description of the Takeoff SOP, Refer to the associated procedure .

- **In addition, apply the following procedure:**

THRUST LEVER.....TOGA

LANDING

Applicable to: ALL

LANDING SOP.....PERFORM

For a detailed description of the Landing SOP, Refer to the associated procedure .

- **In addition, apply the following procedures:**
  - **If the antiskid is inoperative:**

LANDING.....AVOID

AUTO BRK.....SET TO 3

L2 *If the autobrake is inoperative, use the brake pedals to stop the aircraft.*

L1 FLARE.....INITIATE

Perform a firm touchdown after a brief flare.

  - **As soon as the aircraft touches down, apply the following procedures:**

DEROTATION.....INITIATE

L2 *Before lowering the nosewheel on the runway, select maximum reverse thrust to ensure that maximum reverse thrust is applied as soon as possible.*

L1 REV (if available).....MAX

L2 *If necessary, use maximum reverse thrust until the aircraft is fully stopped.*

Note: In snowing conditions, and if the flight crew does not reduce the reversers, visibility may be reduced by snow blowing at low speeds.

L1 AUTO BRK.....MONITOR

L2 *Monitor the autobrake. If necessary, use the brake pedals to stop the aircraft.*

L1 **AT TAXI SPEED**

AT TAXI SPEED SOP..... PERFORM

For a detailed description of the At Taxi Speed SOP, Refer to the associated procedure .

● **In addition, apply the following procedure:**

TAXI SPEED..... LOW

L2 - *Remember that the antiskid is inhibited at very low speeds.*
- *For turns with large nosewheel steering angles (minimum radius):*
  - *Noise and vibrations may be due to wheel skid*
  - *Maintain the speed as low as possible (max 5 kt), to prevent wheel skid and/or an increase in turn radius*
  - *If necessary, use the outer engine and differential braking. Maintain the other engines at idle*
  - *Do not apply symmetrical thrust to prevent wheel skid and/or an increase in turn radius.*
- *If the body wheel steering is inoperative:*
  - *Do not perform brake pivot turns to prevent wheel skid and/or an increase in turn radius*
  - *On slippery or contaminated runways, minimize the tiller angle.*

AFTER LANDING

Applicable to: ALL

AFTER LANDING SOP..... PERFORM

For a detailed description of the After Landing SOP, Refer to the associated procedure .

● **In addition, apply the following procedures:**

FLAPS.....DO NOT RETRACT

L2 *Flaps retraction may damage the structure.*

L1 ● **After engine shutdown, pay attention to the following items:**

EXTERIOR INSPECTION.....PERFORM

L2 *The slats/flaps mechanism must be free of contamination.*

L1 ● **When the slats/flaps mechanism are free of contamination, apply the following procedure:**

GREEN AND YELLOW ELEC PUMP.....ON

FLAPS.....RETRACT

L2 *Monitor slats/flaps retraction on the ECAM page.*

L1 GREEN AND YELLOW ELEC PUMP.....OFF

Intentionally left blank

OVERVIEW

Applicable to: ALL

Flight without cabin pressurization can result of:

- Dispatch under MEL (e.g. both packs inoperative)
- Departure following a structural damage
- Decompression in flight.

The flight crew will decide the flight level, and airspeed depending on:

- The cause of the depressurization
- The distance to fly
- The topographic conditions
- The meteorological conditions, and
- The passengers on board the aircraft.

OXYGEN REQUIREMENTS

Applicable to: ALL

FOR CREW MEMBERS

To obtain the requirements in oxygen for crew members, refer to FAR 121.329 and/or JAR-OPS 1.770, or any other applicable operational regulation.
For more information on oxygen limitations for crew members, *Refer to LIM-35 Minimum Flight Crew Oxygen Pressure* .

FOR PASSENGERS

For oxygen limitations for passengers, *Refer to LIM-35 Minimum Cabin Oxygen Pressure* .

FAILURE OCCURING IN FLIGHT

Applicable to: ALL

In the case of an aircraft decompression in flight, the CAB PRESS EXCESS CAB ALT alert will trigger on the EWD (for more information on this alert, *Refer to PRO-ABN-ECAM-10-21-30-110 CAB PRESS EXCESS CAB ALT*).

FAILURE PRESENT AT DISPATCH

Applicable to: ALL

OPERATIONAL RECOMMENDATIONS

RECOMMENDED ALTITUDE : FL 100 or MSA

If the altitude of the aircraft cabin reaches 13 800 ft , the cabin oxygen masks will automatically drop.

The flight crew must decide the aircraft altitude, depending on:
- *The Minimum Safe Altitude (MSA)*
- *Oxygen requirements*
- *Turbulence, that can be uncomfortable for passengers*
- *Possible low Outside Air temperature (OAT), that can be uncomfortable for passengers, when the aircraft is ventilated by RAM air only.*

AIRSPEED REDUCTION.....CONSIDER

Consider reducing airspeed, to minimize the impact of turbulence on passengers. Use slats and flaps, as necessary.

BEFORE TAKEOFF AND FOR THE WHOLE FLIGHT

- **If both packs are inoperative, or if there is a door failure:**
  PACK 1.....OFF
  PACK 2.....OFF
  RAM AIR..... ON

- **If there is a structural damage:**
  PACK 1..... ON
  PACK 2..... ON
  CAB ALT MODE..... MAN
  CAB ALT TRGT..... CRUISE ACFT ALT

DURING TAKEOFF AND CLIMB

RATE OF CLIMB : LIMIT TO ABOUT 500 ft/min

L2 *This limits the pressure change felt by the passengers, and/or the crew.*

Note: The CAB PRESS EXCESS CAB ALT alert can be triggered by the ECAM during climb. Consider the use of the ECAM CLR key to clear this alert.

L1 AT TOP OF DESCENT

RATE OF DESCENT : LIMIT TO ABOUT 500 ft/min EXCEPT DURING FINAL APPROACH

- **If there is a structural damage:**

  CAB ALT TRGT..... CRUISE ACFT ALT

  The cabin altitude target must be maintained at the cruise aircraft altitude: This ensures that the outflow valves remain open and the cabin differential pressure remains at 0 during descent.

Intentionally left blank

OVERVIEW

Applicable to: ALL

This procedure applies to ferry the aircraft with the landing gear down.
For procedure limitations, and information applicable in the case of in-flight failure of the landing gear retraction, *Refer to PRO-ABN-ECAM-10-32-70 L/G RETRACTION FAULT* .
A ferry flight with the landing gear down is permitted with the gear doors closed.

LIMITATIONS

Applicable to: ALL

- Maximum altitude: 35 000 ft
- VMO/MMO: 245 kt / M 0.62
- Do not fly into expected icing conditions
- Ditching with landing gear down has not been demonstrated
- The flight crew must disregard FMS fuel predictions and other predictions (altitude, speed). Time predictions are valid only when in cruise
- The flight crew must not use:
  - Managed speed (except in approach)
  - The AP/FD CLB and DES modes

PROCEDURE

Applicable to: ALL

PREFLIGHT

VMO/MMO..... 245 kt/M 0.62
VMO-MMO sw .....CHECK ON "L/G DOWN" POSITION

The VMO-MMO switch is located in the avionics compartment.
The flight crew can check the VMO-MMO sw position in the technical logbook. Before flight with gear down, the maintenance personnel must prepare the aircraft and fill in the technical logbook.

FINAL TAKEOFF

VLS+12kt.....MAINTAIN

L2 *This speed is determined in relation with the following constraints:*
- *The speed must guarantee the best climb gradient for takeoff, therefore the minimum speed*
- *The speed must guarantee sufficient manoeuvrability, therefore sufficient aircraft speed*
- *The speed must be easy to manage*

PERFORMANCE

Applicable to: ALL

OVERVIEW

The drag increase due to the landing gear down position affects takeoff, en-route and go-around performance, and also fuel consumption.
The flight must be planned in accordance with this modified performance capability.

TAKEOFF

CONF 1+F is the recommended takeoff configuration.

Note: *Avoid tailwind conditions.*

The T.O. PERF application takes into account the second segment and the final takeoff climb gradient penalty, when the flight crew selects the option LANDING GEAR POSITION EXTENDED in the ACFT STATUS panel/MEL items.
During final takeoff, the flight crew must maintain VLS + 12 kt.

EN ROUTE CONDITION

For the planned takeoff weight, in the case of an engine(s) failure(s), the aircraft is able to clear terrain along the route by :
- 1 000 ft, if the aircraft needs to climb or is in the climb phase, or
- 2 000 ft, if the aircraft is in the descent phase

The conditions must be checked with the PEP AFM module calculation. If en-route conditions cannot be respected, the takeoff weight should be reduced.

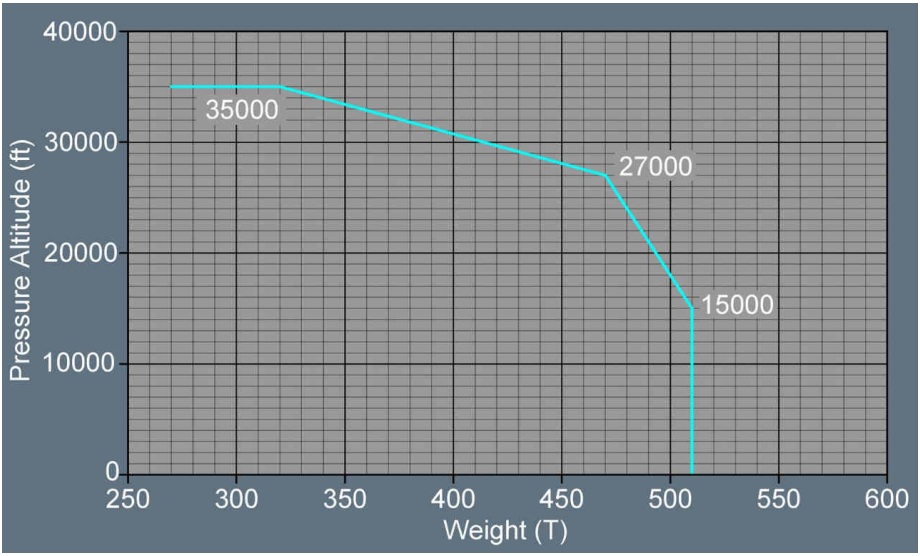
GO-AROUND PERFORMANCE

The LDG PERF application takes into account the go-around gradient penalty, when the flight crew selects the option LANDING GEAR POSITION EXTENDED in the ACFT STATUS panel/MEL items.

FLIGHT PLANNING

MAXIMUM ALTITUDE

The aircraft must remain below the following profile to ensure that at any moment of the flight, VLS is 20 kt below the maximum speed (limited by thrust or VMO/MMO):



CLIMB

Apply maximum climb thrust on all engines.
Climb Speed..... 235KT / 0.59M

CRUISE/DESCENT

Recommended cruise/descent speed.....235KT/ 0.59M
The ceiling with one or two engine inoperative may be a limiting factor, and the choice of the route should reflect this concern.

ENGINE FAILURE

The flight crew can determine the drift down ceiling with engine(s) inoperative by using the IN-FLT PERF application.
Drift down thrust (thrust lever)..... Maximum Continuous (MCT)
Drift down speed.....VLS + 12kt

HOLDING

CLEAN configuration at green dot speed is recommended for holding.
The flight crew can determine the fuel consumption by using the IN-FLT PERF application, HLD thumbnail.

Intentionally left blank

HIGH ALTITUDE AIRPORT OPERATION

Applicable to: ALL

TAKEOFF FROM AIRPORT AT, OR ABOVE 9 000 FT OF PRESSURE ALTITUDE

BEFORE TAKEOFF

Spurious triggering of CAB PRESS EXCESS CAB ALT alert may occur at aircraft power up. Cancel the alert.

ONE OXYGEN MASK.....DON / N SELECTION

At least one pilot must use the oxygen mask from takeoff, and until cruise.

L2 *During that period, the triggering threshold of CAB PRESS EXCESS CAB ALT alert changes from 9 550 ft to takeoff elevation + 1 000 ft .*

L1 *The use of the mask increases the oxygen consumption. The minimum flight crew oxygen pressure must be increased: Refer to Limitations / Fixed Oxygen System for Cockpit .*

AT TOP OF CLIMB

LDG ELEVN..... CHECK

Check that the LDG ELEVN appears on the CRUISE page.

OXYGEN MASK.....REMOVE / 100% SELECTION / STOW

Remove the oxygen mask, set the N/100% selector on 100%, and stow the mask.

L2 *For more information on mask stowing, Refer to DSC-35-20-30 How to Stow the Mask .*

L1 LANDING ON AIRPORT AT, OR ABOVE 9 000 FT OF PRESSURE ALTITUDE

CRUISE

- **If CAB ALT unduly increases above 8 000 ft :**

  CABIN ALT MODE.....MAN
  CABIN ALT TRGT..... 8 000 ft

  In the case of a step descent, or a turbulence, the pressurization system may consider that the aircraft is in descent.

L3 The pressurization descent phase occurs, when the aircraft rate of descent is greater than 150 ft/min .

L1 The pressurization system will then control the pressure to the landing field elevation.

- **Just after top of descent :**

  CABIN ALT MODE..... AUTO

AT TOP OF DESCENT

LDG ELEVN..... CHECK

Check that the LDG ELEVN appears on the CRUISE page.

When the aircraft is descending, the pressurization system controls the pressure to the landing field elevation.

L3 *The landing field elevation comes from the FMS .*

L1 ONE OXYGEN MASS.....DON / N SELECTION

At least one pilot must use the oxygen mask continuously until landing.

L2 *During that period, the triggering threshold of CAB PRESS EXCESS CAB ALT alert changes from 9 550 ft to the landing field elevation + 1 000 ft .*

L1 *The use of the mask increases the oxygen consumption. The minimum flight crew oxygen pressure must be increased: Refer to Limitations / Fixed Oxygen System for Cockpit .*

FLIGHT OVER MOUNTAINOUS AREA

Applicable to: ALL

INTRODUCTION

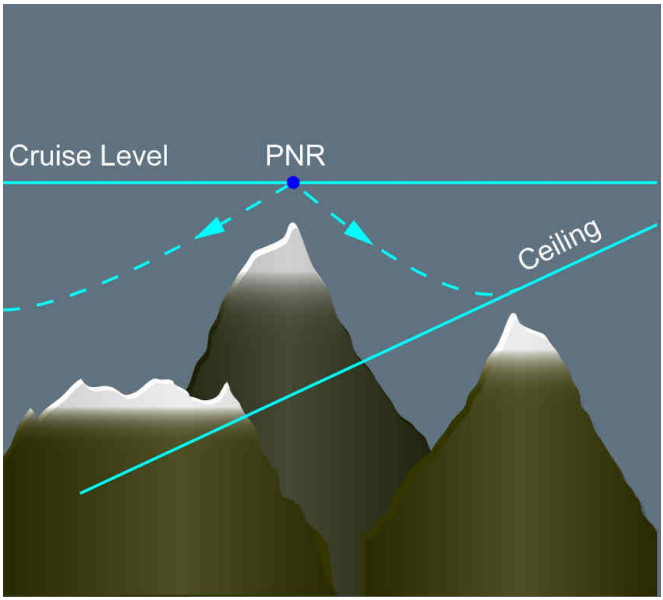
The Operator must take into account two failures for en-route obstacle clearance over mountainous area:

- Engine failure that forces a descent to a lower cruise level
- Depressurization that requires a descent to FL 100 before no more oxygen from the passenger oxygen system is available.

ENGINE FAILURE

If the standard strategy does not enable the aircraft to clear obstacles, the flight crew must apply a drift down procedure. If an engine failure occurs at any point on the route, the net flight path must clear the obstacles on the drift down part by 2 000 ft , and on the climb part by 1 000 ft .
For procedures to be applied in the different strategies, *Refer to Performance/Diversion Strategy* .
If the aircraft cannot clear the en-route obstacles, a point of no-return (PNR) must be determined.

Engine Failure



If an engine failure occurs after the PNR , the aircraft must drift down on course. If the failure occurs before the PNR , the aircraft must turn back.

DEPRESSURIZATION

In the case of depressurization, the passengers receive oxygen through individual oxygen masks. The flight crew has to perform an emergency descent, in accordance with a profile. This profile depends on the fixed oxygen system for the cabin: *Refer to Limitations/Fixed Oxygen System for Cabin* .

CONCLUSION

A detailed study of each route over mountainous area must show that the net flight path with one engine out, and that the performance of the fixed oxygen system for cabin enable the aircraft to clear the obstacles by 1 000 ft in climb, and by 2 000 ft in cruise or descent.
If the aircraft in these circumstances cannot clear the obstacles on the route, the Operator must determine a PNR , and must establish diversion procedures.

GENERAL

Applicable to: ALL

Operators that intend to perform a three-engine ferry flight should obtain an operational approval from the appropriate authority.

The operator must refer to:
- The Aircraft Flight Manual (AFM) that provides the limitations to perform a three-engine ferry flight, *Refer to AFM/APP-3EFF-GEN General*
- The Minimum Equipment List (MEL) that provides the conditions to perform a three-engine ferry flight, *Refer to MEL/SPE-OPS-3EFF-PRE Preamble* .

The flight crew must be qualified and trained on the three-engine ferry flight operations.

TECHNICAL CONDITION OF THE AIRCRAFT

Applicable to: ALL

RESET BUTTON

In accordance with the Aircraft Maintenance Manual (AMM) procedure, the Engine Interface Power Management (EIPM) reset button in relation to the inoperative engine must be pulled on the reset panel:

- If engine 1 is inoperative: ENG 1 EIPM 2...CHECK PULLED
- If engine 2 is inoperative: ENG 2 EIPM 1...CHECK PULLED
- If engine 3 is inoperative: ENG 3 EIPM 2...CHECK PULLED
- If engine 4 is inoperative: ENG 4 EIPM 1...CHECK PULLED.

When the EIPM reset button of the inoperative engine is pulled, the associated FADEC is permanently powered and the anti-ice fault light is on.

C/B ECAM PAGE

In accordance with the AMM procedure, the circuit breakers of the ignitors of the inoperative engine must be tripped on the C/B ECAM page:
- IGNITOR B ENG 1(2)(3)(4)...CHECK TRIPPED
- IGNITOR ENG 1(2)(3)(4) ESS...CHECK TRIPPED.

MEL

The flight crew must check that all inoperative systems are not required as fully operative for dispatch.
All the systems that are required for dispatch are listed in the MEL . *Refer to MEL/SPE-OPS-3EFF-LIM-PROC-AC-SYS-LIM Aircraft Systems Limitations* .

PERFORMANCE APPLICATION

The flight crew can use the T.O PERF application to compute the takeoff performance, by selecting the "1 engine out ferry flight" item in the MEL items subpanel of the ACFT STATUS panel.
Before the flight, the flight crew should ensure that the "1 engine out ferry flight" item is activated in the performance application by the performance application administrator.
If the "1 engine out ferry flight" item is not available in the performance application, a specific takeoff chart must be computed for each runway from which a three-engine ferry flight is performed and according to the inoperative engine.

ENGINES

All four engines with complete cowlings must be installed. Any engine may be inoperative.

Prior to the ferry flight, the inoperative engine should be conditioned in accordance with the AMM procedure, in one of the following configurations:
- Windmilling: Fan rotor and core engine freely rotating in the airflow, or
- Core blank: Fan blades removed and core engine blanked by maintenance equipment.

It is the airline responsibility to choose the engine configuration according to the engine damage (e.g. rotating parts, vanes, abradable seals).

THRUST REVERSERS

If the inoperative engine is an inner engine, the associated thrust reverser must be inhibited in accordance with the AMM procedure.

FUEL USED

If the FU indication of the inoperative engine does not indicate zero, the maintenance crew must reset it to zero according to the AMM procedure.

OPERATING LIMITATIONS

Applicable to: ALL

GENERAL

The following gives only the additional restrictions applicable to three-engine ferry flight. Where not explicitly mentioned, the basic limitations remain valid throughout the three-engine ferry flight.

FLIGHT DURATION

FERRY FLIGHT WITH CORE BLANK

No limitation on flight duration.

FERRY FLIGHT IN WINDMILLING

The duration of the ferry flight only depends on the flight time performed after the engine failure during the previous flight.

Note: The duration of the ferry flight does not depend on the status of the engine lubrication system.

The total flight time (with engine failed during the previous flight plus the ferry flight) must not exceed 25 h .

CG LIMITATION

The maximum aft CG at takeoff is limited to 40 % .
After the refuel, if the CG is out of the takeoff limit, the flight crew can start an automatic ground transfer. For more information, *Refer to DSC-28-50-20 AUTOMATIC GROUND TRANSFER* .

TAKEOFF CONFIGURATION

For maximum performance at takeoff, the engines shall not supply bleed air. The packs must be switched off or supplied by APU .
Slats/flaps configuration for takeoff is CONF 1 + F only.

WEATHER CONDITIONS

ICING

Icing conditions must be avoided because the associated engine anti-ice system is not available on the inoperative engine.

RUNWAY CONDITION

Takeoff is only authorized on dry or wet runway.
Takeoff is not authorized on contaminated runway.

CROSSWIND

The maximum crosswind allowed for takeoff is 10 kt .

LANDING GEAR

Dispatch for a flight with the landing gear down is not authorized.

POWER PLANT

Only TOGA takeoff thrust is authorized.
Flexible or derated takeoff thrust is not authorized.

NORMAL OPERATING PROCEDURES

Applicable to: ALL

GENERAL

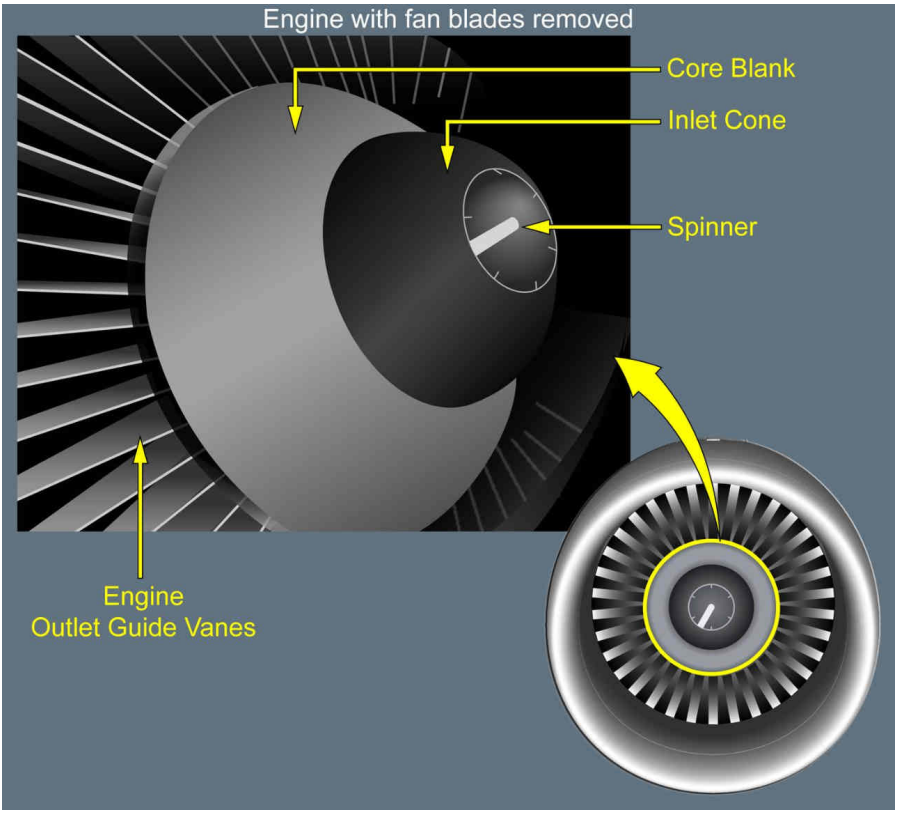
The standard operating procedures remain applicable for a three-engine ferry flight unless here after modified.

EXTERIOR WALKAROUND

No particular check is required regarding the inoperative engine (i.e. windmilling and core blank configurations). The flight crew should apply the standard exterior walkaround procedure.

L2 If the inoperative engine is in core blank configuration, the maintenance crew installs the following equipment, in accordance with the AMM procedure:

CORE BLANK CONFIGURATION



L1 COCKPIT PREPARATION

AIR

AIR FLOW selector ..... LO

ELEC

GEN 1(2)(3)(4) ..... OFF

The generator associated with the inoperative engine must be switched off throughout the ferry flight.

The complete AC and DC electrical networks remain supplied. No specific shedding of commercial loads is required.

Note: Associated to the inoperative engine, the ECAM alert ELEC GEN 1(2)(3)(4) OFF triggers 1 min after 1 500 ft AGL .
The flight crew should clear the ECAM and remove the STATUS page.

FUEL

ALL FUEL PUMPS..... ON

As for normal operation all the fuel pumps are selected ON, including the fuel pumps of the inoperative engine.

ALL FUEL CROSSFEEDS.....ON then OFF

Check on the FUEL SD page that crossfeed valves correctly open then close.

FUEL USED OF THE FAILED ENGINE.....CHECK ZERO

If the Fuel Used indication of the failed engine does not indicate zero, the maintenance crew must reset it to zero according to the AMM procedure.

HYD

ENG 1(2)(3)(4) PMP A..... OFF
ENG 1(2)(3)(4) PMP B..... OFF

The engine driven pumps A and B of the inoperative engine must be set to OFF.

Note: When the inoperative engine is in windmilling, do not push the ENG FIRE pb since that may cause hydraulic pump damage.

CARGO AIR COND

ALL ISOL VALVES pb-sw .....OFF

MFD SURV

TCAS pb ..... TA ONLY

MFD FMS INITIALIZATION

On ground, the FMS fuel predictions are different from the predictions of the Computerized Flight Plan (CFP): The CFP fuel predictions are based on one engine inoperative while the FMS does not detect that one engine is inoperative on ground when the engines are not running. As a result, on ground, the FMS fuel predictions consider all engines operative and normal operating speeds. After takeoff, the FMS automatically detects that one engine is inoperative, and computes the FMS fuel predictions accordingly.
For more information on FMS predictions with one engine inoperative, *Refer to DSC-22-FMS-10-60 General* .

The FMS detects the inoperative engine during the takeoff phase. Therefore, the THRUST RED altitude and the ACCEL altitude of the T.O panel of the FMS ACTIVE/PERF page have no effect on the aircraft guidance.
After liftoff, in IMC , fly a "standard" engine inoperative procedure, e.g. level acceleration at the recommended altitude or 1 000 ft AGL , if obstacles permit. In VMC , a slow acceleration toward climb speed can be performed reaching the normal acceleration altitude.

Note: *The EO ACCEL altitude of the T.O panel of the FMS ACTIVE/PERF page is only a reminder.*

For more information on the procedure to apply with one engine out during the initial climb-out, *Refer to PRO-ABN-NECA-10-GENGF Engine Failure after V1 - Proc* .

ENG

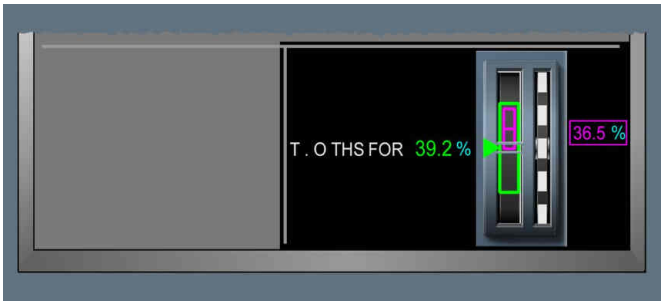
If the inoperative engine is an INNER engine:
- ENG 2(3) REVERSER INHIBITED ECAM alert triggers at power up
  The flight crew should clear the ECAM and remove the STATUS page.
- ENG 2(3) REVERSER CTL FAULT ECAM alert triggers at 1 500 ft AGL .
  The flight crew should clear the ECAM and remove the STATUS page.

AFTER ENGINE START

Position the pitch trim more nose down, i.e. at the lower end of the magenta band that is displayed on the PFD .

L2 Setting the pitch trim at the lower end of the magenta band improves the directional efficiency during the takeoff run.

Pitch Trim Setting



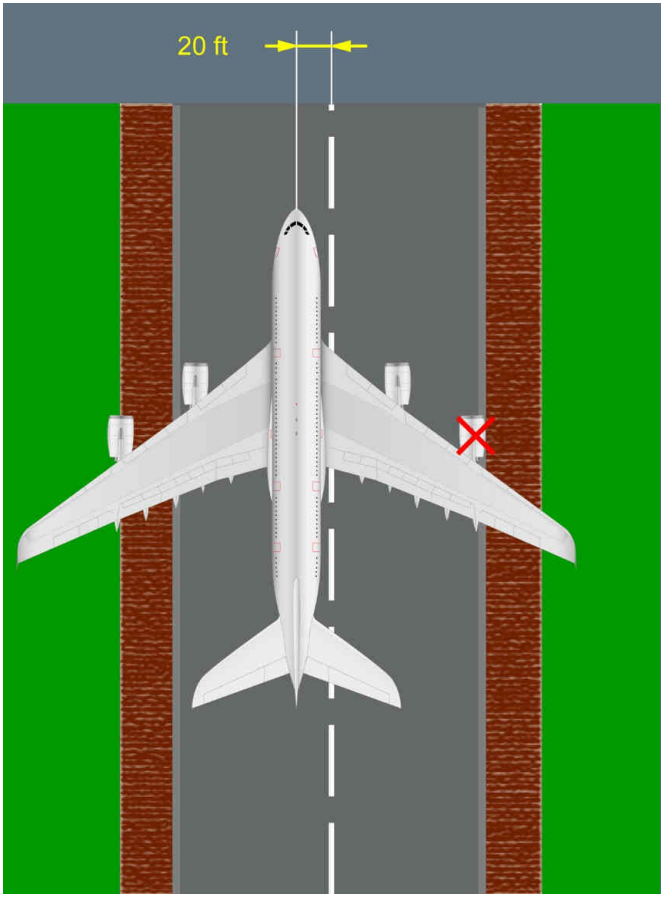
L1 BEFORE TAKEOFF

PACKS 1+2.....OFF or SUPPLIED BY APU BLEED

TAKEOFF PROCEDURE

Align the aircraft with a 20 ft offset toward the side where two engines are operative.

Aircraft Alignment on runway



Specific takeoff thrust setting procedures have been defined for the two following cases:

- **Takeoff procedure with an INNER engine inoperative :**

  Prior to brake release: Apply 25 % THR on the operative engines.

  After brake release: Apply TOGA on the two outer engines.

From 60 kt : Progressively accelerate the operative inner engine to reach:
- CL at 100 kt ,
- TOGA at 120 kt .

Note: - *Do not rush to set the power on the operative inner engine*
- *At takeoff thrust application, the ECAM alerts ENG 2(3) SHUT DOWN and *ELEC and *BLEED secondary failures trigger.*
The flight crew should clear the ECAM and remove the STATUS page.

At VR , progressively rotate toward a pitch attitude of 10 ° .

After liftoff, center the beta target.

For more information on procedure to apply with one engine out during the initial climb-out, *Refer to PRO-ABN-NECA-10-GENGF Engine Failure after V1 - Proc* .

■ **Takeoff procedure with an OUTER engine inoperative :**

Prior to brake release: Apply 25 % THR on the inner engines and 20 % THR on the operative outer engine.

After brake release: Apply TOGA on the two inner engines.

From 60 kt : Progressively accelerate the operative outer engine to reach:
- 50 % THR at 100 kt ,
- CL at 120 kt ,
- TOGA at 140 kt .

Note: - *Do not rush to set the power on the operative outer engine*
- *At takeoff thrust application, the ECAM alerts ENG 1(4) SHUT DOWN and *ELEC and *BLEED secondary failures trigger.*
The flight crew should clear the ECAM and remove the STATUS page.

At VR , initiate the rotation toward a pitch attitude of 10 ° .

After liftoff, center the beta target.

For more information on procedure to apply with one engine out during the initial climb-out, *Refer to PRO-ABN-NECA-10-GENGF Engine Failure after V1 - Proc* .

AFTER TAKEOFF, WHEN IN CLEAN CONFIGURATION

● **If the APU is used to supply the air conditioning during takeoff:**
APU BLEED pb-sw ..... OFF
APU MASTER sw ..... OFF

● **If the takeoff is performed with both packs OFF:**
PACKS 1 + 2 ..... ON

IN FLIGHT

During the main fuel transfers from the transfer tanks to the feed tanks, the FQMS automatically balances the fuel.
When inner and mid tanks are empty, the FQMS can no longer balance the fuel. Subsequently, due to the inoperative engine, this may lead to a fuel imbalance and the ECAM alert FUEL WINGS NOT BALANCED may trigger. Apply the associated ECAM procedure.
For more information, *Refer to PRO-ABN-ECAM-10-28-390 FUEL WINGS NOT BALANCED* .

L2 *Note: The ECAM alert FUEL WINGS NOT BALANCED triggers as soon as there is an imbalance of more than 6 600 lb between two symmetric feed tanks.*

L1 When the fuel balancing is completed, the ECAM alert FUEL WINGS BALANCED triggers. Apply the associated ECAM procedure.
For more information, *Refer to PRO-ABN-ECAM-10-28-400 FUEL WINGS BALANCED*

L2 *Note: The ECAM alert FUEL WINGS BALANCED triggers as soon as there is an imbalance of less than 1 100 lb between two symmetric feed tanks.*

L1 Taking into account that the fuel consumption is approximately 6 600 lb/h per engine, the ECAM alert FUEL WINGS NOT BALANCED may trigger every hour. Apply the associated ECAM procedure.

ABNORMAL OPERATING PROCEDURES

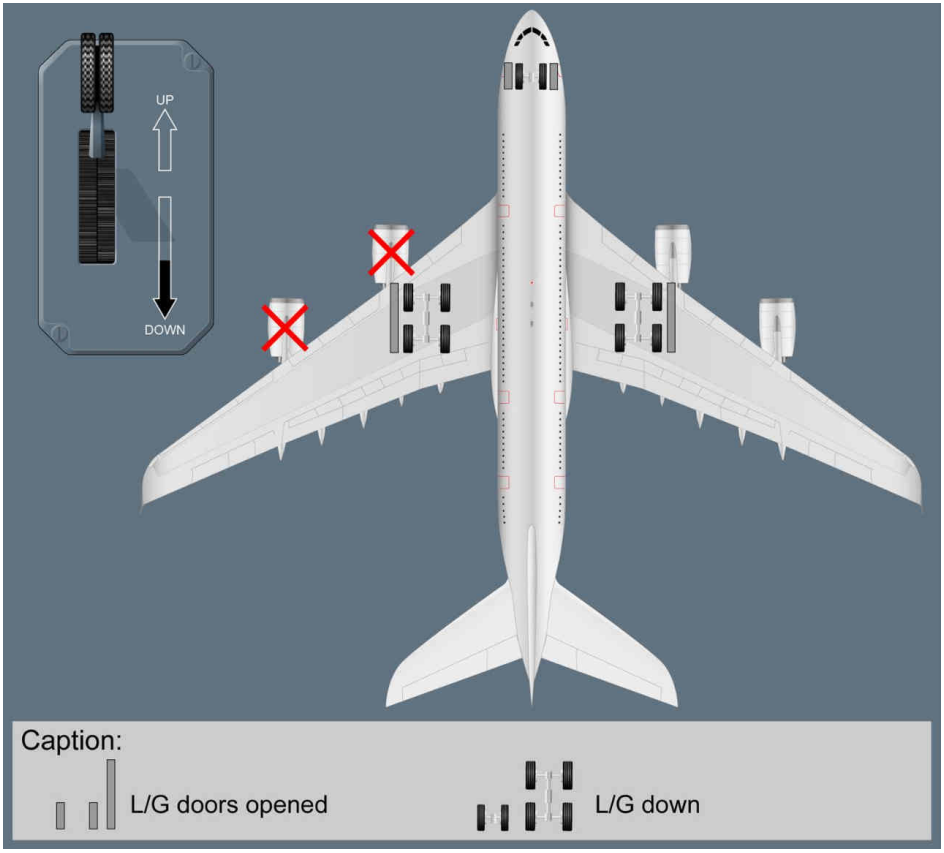
Applicable to: ALL

The abnormal and emergency operating procedures remain applicable for three-engine ferry flight, *Refer to Abnormal and Emergency Procedures* .

In the case of dispatch with one inoperative engine, if the remaining engine on the same wing fails during takeoff one hydraulic system is lost.
With one hydraulic system inoperative, depending on the hydraulic system failure, some landing gears do not retract and some landing gear doors remain open, when the flight crew set the L/G lever to the UP.
However , the flight crew must set to UP the L/G lever in order to reduce the drag.

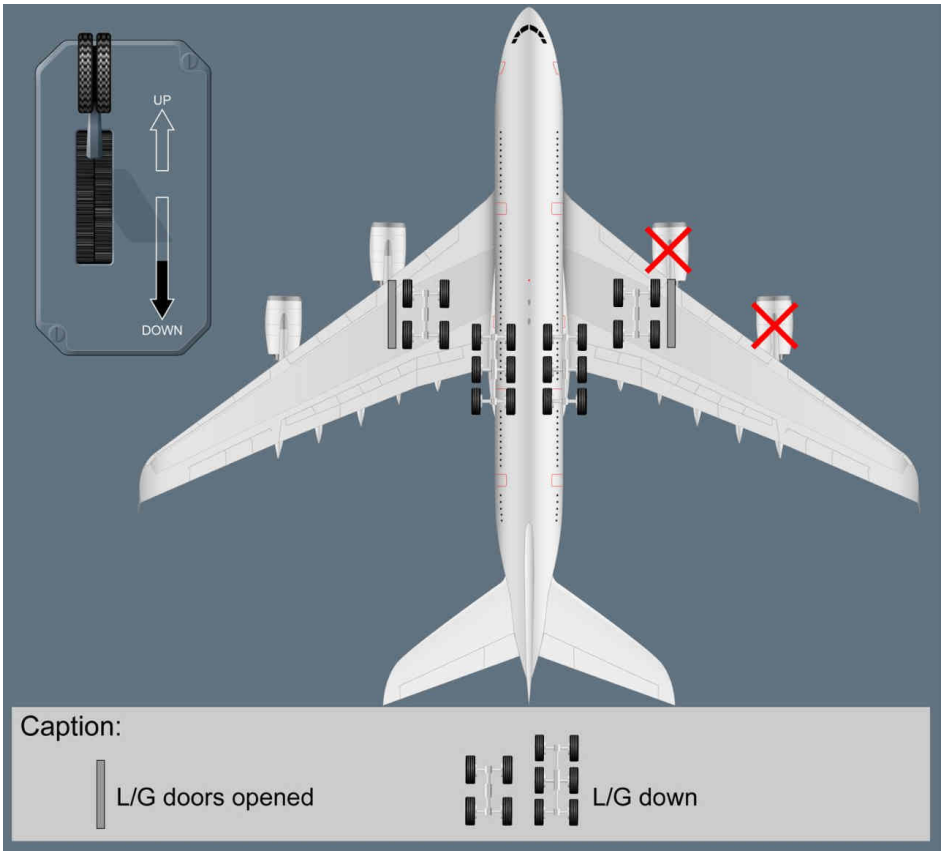
L2 - Landing gear position when L/G is retracted after the loss of engines 1 and 2:

Two Engine Inoperative Same Side (Engines 1 and 2)



- Landing gear position when L/G is retracted after the loss of engines 3 and 4:

Two Engine Inoperative Same Side (Engines 3 and 4)



L1 Use VLS + 5 kt as final takeoff speed.

L2 *VLS + 5 kt corresponds to the Green Dot speed with two engines inoperative same side, some landing gears not retracted, and some landing gear doors open.*

L1 For landing: Use normal landing gear extension.

PERFORMANCE

Applicable to: ALL

REQUIREMENTS

The regulatory requirements that are usually applicable are replaced by the following requirements, for the three-engine ferry flight.

TAKEOFF

For takeoff distance and takeoff run determination, no additional engine failure is taken into account. The required TOD and TOR are equal to 1.15 of the distance covered from the brake release to a point at which the aircraft is at 35 ft . Credit for clearway cannot be taken into account.

The VSTOP is the maximum speed to which the aircraft can accelerate with all operative engines operating, and then stop within the available accelerate-stop distance.

VR must be above 1.03 VMCA -2.
V2 must be above 1.07 VMCA -2.

Note: - *If after VSTOP a second engine fails, the criterion " 35 ft above the takeoff surface at V2 speed" may not be satisfied.*
- *The performance application calculates a VSTOP instead of a V1 . However, the performance application still displays VSTOP as V1 .*

Differentiation between inoperative inner and outer engine is taken into account in the AFM , but inoperative outer engine leads to the most adverse performance.
No differentiation between the ferry flight in windmilling and with core blank is considered in the AFM , the performance is the same.

There is no requirement concerning the first segment.

The following takeoff flight path requirements are based on the failure of a second engine during the takeoff phase. All performance data are based on dispatch with one RH engine inoperative and failure of the adjacent (RH) engine that corresponds to the critical case in terms of drag. This scenario results in non-retraction of wing and body gears.

- Second segment requirement: A minimum gradient of 1.5 % at 400 ft height is required
- Final takeoff requirement: A minimum gradient of 1.2 % is required.

The net takeoff flight path is the gross flight path reduced by a gradient of 0.5 % .

EN ROUTE

The en route flight path is considered with two engines inoperative on the same wing and gear up.

The net gradient is the gross gradient decreased by 1 % .

APPROACH AND LANDING

There is no requirement concerning the approach climb.
For landing climb, a minimum climb gradient of 2 % is required with all three operative engines, landing configuration, gear down, thrust available 8 s after initiation of throttle movement from idle to TOGA detent, and a speed not less than 1.23 Vs1g and VMCL .
The landing distance calculation does not basically account for the two engines inoperative case. In the case of second engine failure in flight, refer to displayed ECAM procedure for associated system loss (loss of spoilers if the engine on the same wing fails and/or thrust reversers) for landing performance computation.

For additional information:
- *Refer to PRO-ABN-ECAM-10-70-272 ENG TWO ENGs OUT ON SAME SIDE*
- *Refer to PRO-ABN-ECAM-10-70-273 ENG TWO ENGs OUT ON OPPOSITE SIDE* .

PERFORMANCE DATA

FUEL PLANNING

Fuel consumption is the same with the inoperative engine in windmilling or in core blank configuration.

The recommended speeds are:
- For climb:
  - 250 kt below FL 100 if ATC speed limitations are applicable
  - 300 kt above FL 100
  - M 0.80 above the cross-over altitude.
- For cruise: M 0.80
- For descent:
  - M 0.80
  - 300 kt
  - 250 kt

TAKEOFF

It is not authorized to take off with tailwind.
The flight crew can use the TO PERF application to compute the takeoff performance, by selecting the "3 engine ferry flight" MEL item in the takeoff performance application of the OIS .

Note: *Before the flight, ensure that the "3 engine ferry flight" MEL item has been activated in the performance application by the performance application administrator.*
For all runways intended to be operated for "3 engine ferry flight", the performance application administrator should define a runway plus shoulders width of at least 58 m in the airport database to ensure that the flight crew can perform the performance takeoff computation.

If the "3 engine ferry flight" MEL item is not available in the performance application, a specific takeoff chart must be computed for each runway from which a three engine ferry flight is performed and according to the inoperative engine.

EN ROUTE

The flight crew can use the IN-FLT PERF application to compute high speed performance in the case of three engine ferry flight . All the functions and modules of the IN-FLT PERF application are available.
In the case of second engine failure, the DES module of the IN-FLT PERF application provides the drift down ceiling.

APPROACH AND LANDING

The landing climb performance is never limiting:
- For airports elevation up to 8 000 ft and ISA + 25 °C in CONF FULL
- For airports elevation up to 8 000 ft ISA + 30 °C in CONF 3.

For higher airport elevations or higher delta ISA , the corresponding maximum limiting weight must be determined using the performance programs.

Intentionally left blank

OVERVIEW

Applicable to: ALL

The Reduced Vertical Separation Minimum (RVSM) airspace is any airspace or route between FL 290 and FL 410 (inclusive), where aircraft are vertically separated by 1 000 ft, instead of 2 000 ft.

RVSM REQUIREMENTS

Applicable to: ALL

A380 aircraft systems are designed to comply with the design criteria of the JAA Temporary Guidance Leaflet No. 6 (JAA TGL 6 - EASA Regulations), and the FAA Guidance Material for RVSM operations No. 91–RVSM.
The AFM provides the statement of RVSM capability.

OPERATIONAL APPROVAL

In addition to the RVSM capability statement provided in the AFM, Operators must obtain operational approval from their national airworthiness authorities, in order to operate within the RVSM airspace.
The above-mentioned EASA and FAA documents also indicate the requirements for obtaining operational approval.

REQUIRED EQUIPMENT AND FUNCTIONS

The RVSM regulation requires that the following equipment or functions be operative:

- Two ADR s
- One transponder
  For associated MEL dispatch conditions, *Refer to MEL/MI-34-71 Transponder* .
- One autopilot function

  For associated MEL dispatch conditions:
  - *Refer to MEL/MI-22-10 Autopilot*
  - *Refer to MEL/MI-22-10 Sidestick AP Locking Device* .
  - *Refer to MEL/MI-22-10 Rudder Pedals AP Locking Device* .
- Two PFD s
- One AFS CP channel or AFS CP backup (for the altitude target selection and the OP CLB or OP DES mode engagement)
- One FWS (for the altitude alert function).

MAXIMUM DIFFERENCES BETWEEN ALTITUDE INDICATIONS

		Comparison of Altitude Indications (ft)		
Flight Level	Speed or Mach Number	ADR 1 and ADR 2 (on the PFD)	ADR 3 and ADR 1(2) (on the PFD)	ISIS and ADR 1(2)(3)
Ground Check	-	20	20	30
FL 50	250 kt	55	60	120
FL 100	250 kt	60	70	140
FL 200	320 kt	120	125	220
FL 300	M 0.85	150	150	320
FL 410	M 0.85	150	150	360

RVSM PROCEDURE

Applicable to: ALL

For flights in RVSM airspace, the flight crew must apply the standard or abnormal and emergency procedures, in addition to the following RVSM procedures:

FLIGHT PREPARATION

The flight crew must take into account the conditions that may affect operations in RVSM airspace, including:

RVSM APPROVAL.....CHECK

L2 *Verify that the airframe is approved for RVSM operations.*

L1 WEATHER.....CHECK

L2 *Review the weather forecasted for the flight route. If severe turbulence is expected, this may affect the ability to maintain aircraft altitude.*

L1 REQUIRED EQUIPMENT FOR RVSM.....CHECK

L2 *Check that all the required equipment is operative (MEL).*
The flight crew should review the maintenance logs and forms, in order to ensure that the equipment required for RVSM is satisfactory.

L1 ALTITUDES.....CHECK

L2 *Check that the difference between each altitude indication (in the QNH reference) and the airport elevation is less than 75 ft .*
On ground, check that at least two of the main altitude indications are within the specified tolerance. For more information, Refer to Maximum Differences Between Altitude Indications .

IN FLIGHT

BEFORE ENTERING RVSM AIRSPACE

REQUIRED EQUIPMENT FOR RVSM.....OPERATIVE

L2 *If any of the required equipment fails before the aircraft enters RVSM airspace, the flight crew must request new clearance, to avoid this airspace.*

L1 ALTITUDES.....CHECK

L2 *Check that the difference between two of the main altitude indications (in the standard baro setting) is less than the specified tolerance. For more information, Refer to Maximum Differences between altitude indications.*

L1 ● **If only two ADRs are operative:**
ALTITUDES ON PFD and STBY ALTITUDE.....RECORD

L2 *This information may be useful, in the case of subsequent PFD altitude discrepancy or altimeter failure.*

L1 **IN RVSM AIRSPACE**

AP.....KEEP ENGAGED

L2 *Ensure that autopilot is engaged for cruise, and for flight level changes.*

L1 AP GUIDANCE.....MONITOR

L2 *During flight level transitions, do not exceed or go below the assigned flight level by more than 150 ft .*

L1 ● **Approximately every hour:**
ALTITUDES.....CHECK

L2 *Check that the difference between two of the main altitude indications is less than the specified tolerance. For more information, Refer to Maximum Differences Between Altitude Indications.*
Regular checks of the flight deck instruments should be sufficient.
Use the transponder and the autopilot, that are associated with any ADR that is within the tolerance. AP 1 and XPDR 1 use ADIRS 1, AP 2 and XPDR 2 use ADIRS 2.

AT THE END OF THE FLIGHT

ANY MALFUNCTIONS or DEVIATIONS.....REPORT

L2 *Report any malfunction of the systems that enable the aircraft to maintain altitude, including:*
- *Any malfunction or loss of required equipment*
- *Any deviation involving the functions that enable the aircraft to maintain altitude.*

ABNORMAL AND EMERGENCY PROCEDURES

ATC..... NOTIFY

When the aircraft is in RVSM airspace, the flight crew must notify the ATC of the following situations, because they may affect the aircraft's ability to maintain the flight level:

- *The failure of both autopilots*
- *The loss of altimeter system redundancy (i.e. only one altitude information remaining)*
- *An excessive discrepancy in altitude indications, and no way to identify the valid indication*
- *The failure of any other equipment, that affects the aircraft's ability to maintain the flight level*
- *The encounter of greater than moderate turbulence.*

If the flight crew cannot notify the ATC, or obtain ATC clearance, before deviating from the assigned flight level, they should follow the established contingency procedure and obtain ATC clearance as soon as possible.

L2 *Note: Appendix 4 of the JAA TGL 6 (EASA Regulations), and Appendix 5 of the FAA 91-RVSM (FAA Regulations), provide detailed Operator guidelines,, on the content and development of contingency procedures.*

OVERVIEW

Applicable to: ALL

Regulations require a system for aircraft navigation, in order to fly within a specific airspace, sometimes referred to as Required Navigation Performance (RNP) airspace.

The navigation system must comply with:
- The RNAV functionality criteria
- The flight guidance criteria
- The navigation position accuracy and integrity criteria.

When referring to RNP–X, X is the navigation accuracy value expressed in nautical miles (nm). The aircraft position error must be below the X value during 95 % of the flight time.

An RNP value is associated with:
- An airspace, or
- A route, or
- A SID, or
- A STAR, or
- An RNAV approach, or
- A RNAV missed approach procedure.

Several navigation systems may be necessary, depending on the RNP value and on the airspace environment (ground radio NAVAID).
It may also be necessary for Operators to obtain operational approval from the airline's airworthiness authority.
The AFM provides the statement of RNP capability.

NAVIGATION SYSTEM CAPABILITY

Applicable to: ALL

The aircraft navigation systems meet the certification requirements of the FAA AC 20–130A and TSO C 129A in class C1 (for a navigation system with multiple sensor inputs, including GPS). The navigation systems also comply with the airworthiness requirements of the following regulations:

- JAA Temporary Guidance Leaflet (TGL) 2 for B-RNAV (5 nm accuracy)
- JAA TGL 10 for P-RNAV (1 nm accuracy)
- FAA Advisory Circular (AC) 90–100 for US RNAV SID and STAR
  - RNAV-2 (2 nm accuracy)
  - RNAV-1 (1 nm accuracy)
- FAA Order 8400.12A, applicable to RNP–10 operations in oceanic and remote areas: Eligibility is based on paragraph 12.0, 12.b (1) or 12.b (5)

- FAA Order 8400.33, applicable to RNP–4 operations in oceanic and remote areas
- EUROCAE ED75A/DO236A, apart from vertical performance.

RNP CAPABILITY

Applicable to: ALL

To comply with a specific RNP procedure, the FMS estimated position accuracy, also called the Estimated Position Uncertainty (EPU), must be lower than the RNP value associated with the procedure. This depends on the selected mode for FMS navigation (GPS , DME /DME, VOR /DME or IRS).
The FMS POSITION/MONITOR page of the MFD displays the RNP and the EPU , and provides the HIGH/LOW accuracy indication. For more information, *Refer to FMS/Navigation Accuracy* .

The RNP on the FMS POSITION/MONITOR page can be:
- A default value, or
- A coded value that is in the navigation database, or
- A value that is manually entered by the flight crew.

When flying in RNP airspace, the FMS provides the navigation accuracy level (HIGH or LOW) on the FMS POSITION/MONITOR page:
- When HIGH appears, the EPU is less than, or equal to the RNP
- When LOW appears, the EPU is more than the RNP , and:
  - The flight crew must crosscheck the navigation with raw data, if available
  - The flight crew must inform the ATC , if the result of the crosscheck is negative, or if the raw data is not available,

When the aircraft exits RNP airspace, the flight crew must clear the manually-entered RNP .

B-RNAV AIRSPACE, RNAV-5, OR EQUIVALENT

Applicable to: ALL

In European B-RNAV airspace, radio NAVAID coverage is considered to support RNAV–5 accuracy.

Before entering a B-RNAV airspace, the minimum required equipment is:
- One RNAV system, that includes:
  - One FMS
  - One MFD
  - The relevant KCCU

    Note: *To comply with the minimum equipment requirements, it is sufficient for the KCCU to have either an operational Cursor Control Device (CCD), or an operational keyboard.*
  - One VOR for FMS navigation update
    For associated MEL dispatch condition, *Refer to MEL/MI-34-50 VOR* .
  - One DME for FMS navigation update
    For associated MEL dispatch condition, *Refer to MEL/MI-34-50 DME* .
  - One IRS
- Flight plan data on both ND s.

In other equivalent airspaces, other RNP accuracy values such as RNAV-2 are possible.
GPS may be required, depending on what radio NAVAID coverage is available.
For associated MEL dispatch condition, *Refer to MEL/DEL-34-ME1 GPS* .

B-RNAV, RNAV-5, OR EQUIVALENT PROCEDURE

● **If GPS PRIMARY is not available:**

FMS POSITION.....CROSSCHECK

L2 *Periodically crosscheck the FMS position, using NAVAID raw data.*

L1 RNP..... CHECK/ENTER

L2 *The flight crew can manually enter the RNP value, or the equivalent radial (e.g. the radial equivalent to 5 nm XTK accuracy is 6.1 nm) on the FMS POSITION/MONITOR page of the MFD.*

When the aircraft exits RNP airspace, or enters the terminal area, the flight crew should:
- *Revert to the default required accuracy value, or*
- *Enter the appropriate value on the FMS POSITION/MONITOR page.*

L1 ● **If any of the following messages appear on the MFD or ECAM:**

- MFD: NAV ACCUR DOWNGRADED
- MFD: FMS1 / FMS2 POSITION DISAGREE
- MFD: CHECK IRS 1(2)(3) / FMS POSITION
- ECAM: NAV FM / GPS POS DISAGREE
- ECAM: NAV FM / IR POS DISAGREE

NAVIGATION ACCURACY.....CHECK

L2 *Check navigation accuracy using NAVAID raw data, or the FMS POSITION/GPS page of the MFD.*

L1 ■ **If RNP capability is lost, or if both FMS are failed:**

ATC.....NOTIFY

NAVIGATION.....USE CONVENTIONAL METHOD

■ **If only one FMS position is correct:**

NAVIGATION..... RESUME

L2 *Resume navigation using the FMS that provides the correct position.*

In inertial navigation, systems maintain B-RNAV capability (5 nm accuracy) for 2 h regardless of the estimated accuracy value that appears on the MFD.

RNP-10 OR RNP-4 IN OCEANIC OR REMOTE AREAS

Applicable to: ALL

In RNP-10/RNP-4 airspace, the aircraft can fly a long time outside the radio NAVAID coverage.

Before entering RNP-10/RNP-4 airspace, the minimum required equipment is:

- Two RNAV systems, that include:
  - Two FMS

    For associated MEL dispatch conditions:
    ■ *Refer to MEL/MI-22-70 Flight Management Computer*
    ■ *Refer to MEL/MI-22-70 FMS Selector* .
  - Two MFD s
  - Two KCCU s

    Note: To comply with the minimum equipment requirements, it is sufficient for each KCCU to have either an operational Cursor Control Device (CCD), or an operational keyboard.
  - For RNP-10, one GPS , if required due to the duration of flight time outside radio NAVAID coverage
    For associated MEL dispatch conditions, *Refer to MEL/MI-34-50 GPS* .
    For RNP-4, one GPS is required.
  - Two IRS.
- Flight plan data on both ND s.

For more information, also refer to Regional Supplementary Procedures of ICAO Doc 7030 for specific requirements in a particular airspace.

RNP-10/RNP-4 PROCEDURE

RNP..... CHECK/ENTER

L2 *The flight crew can manually enter RNP 10 nm, or the equivalent radial (e.g. the radial equivalent to 10 nm XTK accuracy is 12.2 nm) on the FMS POSITION/MONITOR page of the MFD.*
For RNP-4, the flight crew must manually enter 4.9 nm (i.e. the radial equivalent to 4 nm XTK accuracy).

When the aircraft exits RNP airspace, or enters the terminal area, the flight crew must:
- *Revert to the default required accuracy value, or*
- *Enter the appropriate value on the FMS POSITION/MONITOR page of the MFD.*

L1 ● **If any of the following messages appear on the MFD or ECAM:**

- MFD: FMS1 / FMS2 POSITION DISAGREE
- MFD: CHECK IRS 1(2)(3) / FMS POSITION
- ECAM: NAV FM / GPS POS DISAGREE
- ECAM: NAV FM / IR POS DISAGREE

NAVIGATION .....CHECK

L2 *Check navigation accuracy on the FMS POSITION/MONITOR, FMS POSITION/IRS, and FMS MONITOR/GPS pages of the MFD.*

L1 AP.....USE

L2 *Use the AP that has the valid navigation system (previously checked).*
If the flight crew cannot identify the valid system, they should inform the ATC and obtain NAVAID raw data confirmation as soon as possible.

In inertial navigation, systems maintain RNP−10 capability for 5.7 h, since the last radio update (according to the FAA Notice 8400.12A), regardless of the estimated accuracy value that appears on the MFD.
For RNP-4 with GPS PRIMARY LOST, the RNP-4 capability is maintained until NAV ACCUR DOWNGRADED appears.

L1 ● **If RNP capability is lost, or if both FMS are failed:**
ATC.....NOTIFY

P-RNAV, RNAV-1, OR RNAV-2 TERMINAL PROCEDURES

Applicable to: ALL

In European terminal procedures that require P-RNAV capability, radio NAVAID coverage is considered to support the required accuracy. In all other cases, the terminal procedure may require GPS equipment (refer to the published approach chart).

The minimum equipment that is required, before flying a P-RNAV, or RNAV-1, or RNAV-2 procedure is:

- One RNAV system, that includes:
  - One FMS

    Note: *However, some published approach charts may require two RNAV systems.*

    For associated MEL dispatch conditions if two RNAV systems are required:
    - *Refer to MEL/MI-22-70 Flight Management Computer*
    - *Refer to MEL/MI-22-70 FMS Selector .*

  - One MFD
  - The relevant KCCU

    Note: *To comply with the minimum equipment requirements, it is sufficient that the KCCU has either an operational Cursor Control Device (CCD), or an operational keyboard.*

  - One GPS receiver, or one VOR and one DME (for the navigation update)

    Note: *GPS equipment may be required for some terminal procedures.*

    For associated MEL dispatch conditions:
    - *Refer to MEL/DEL-34-ME1 GPS* , or
    - *Refer to MEL/MI-34-50 VOR* , or
    - *Refer to MEL/MI-34-50 DME* .
  - Two IRS
  - One FD engaged in the NAV mode.
    For associated MEL dispatch conditions, *Refer to MEL/MI-22-10 Flight Director* .

  For the terminal procedures with legs below the Minimum Safety Altitude (MSA), or with legs that may not have sufficient radar coverage, two RNAV systems may be required by the published procedure chart.
- Flight plan data on both ND s.

P-RNAV, RNAV-1, OR RNAV-2 PROCEDURE

The FMS navigation database provides the terminal procedure (RNAV SID, RNAV STAR, RNAV TRANSITION, ...) of the flight plan. The flight crew must check the terminal procedure by comparing the published approach charts with the waypoint sequences, tracks, distances, and altitude or speed constraints (on the F-PLN page).
The flight crew must not modify the procedure that is provided by the navigation database, unless required by the ATC (DIR TO, radar vectoring, insertion of waypoints from the navigation database).

■ **If GPS is required for the P-RNAV, RNAV-1, or RNAV-2 procedure:**

GPS PRIMARY..... CHECK AVAILABLE

L2 *Before beginning the procedure, verify that GPS PRIMARY is available: GPS PRIMARY must appear on the FMS POSITION/MONITOR page of the MFD.*

L1 ■ **If GPS PRIMARY is not available:**

ATC..... NOTIFY

L2 *Request another procedure that does not require GPS.*

L1 ■ **If GPS PRIMARY is lost in flight:**

ATC..... NOTIFY

L2 *Follow ATC instructions.*

L1 ■ **If GPS is not required for the P-RNAV, RNAV-1, or RNAV-2 procedure:**

GPS PRIMARY ..... CHECK AVAILABLE

L2 *Before beginning the procedure, check if GPS PRIMARY is available: GPS PRIMARY must appear on the FMS POSITION/MONITOR page of the MFD.*

L1 ● **If GPS PRIMARY i s not available:**

FM POSITION..... CROSSCHECK

L2 *Before beginning the procedure, crosscheck the FMS position using NAVAID raw data.*

L1 RNP FOR APPROACH..... CHECK/ENTER

L2 *Check and enter the RNP value in the RNP entry field, of the FMS POSITION/MONITOR page of the MFD.*

When completing the terminal procedure, the flight crew must:
- *Revert to the default required accuracy, or*
- *Enter the appropriate value on the FMS POSITION/MONITOR page.*

L1 HIGH ACCURACY..... CHECK

■ **If the following messages appear on the MFD or ECAM, or if both FMS are failed:**

- NAV ACCUR DOWNGRADED on both NDs

L2 *Note: If only one ND displays the NAV ACCUR DOWNGRADED message, the flight crew may continue navigation using the other FMS.*

L1
- MFD: FMS1 / FMS2 POSITIONS DISAGREE
- ECAM: NAV FM / GPS POS DISAGREE

ATC.....NOTIFY

L2 *Inform the ATC of the RNP capability loss, and follow ATC instructions.*

BASIC RNP 0.3 APPROACH

Applicable to: ALL

The navigation systems comply with the ED75/DO-236 requirements for RNP 0.3 in approach. These requirements support basic RNP 0.3 approaches designed under ICAO PANS OPS or TERPS "standard" criteria (not RNPAR or SAAAR).

Before flying an RNP 0.3 procedure, the minimum required equipment is:

- One RNAV system, that includes:
  - One FMS

    Note: *However, some published approach charts may require two RNAV systems.*

    For associated MEL dispatch conditions if two RNAV systems are required:
    - *Refer to MEL/MI-22-70 Flight Management Computer*
    - *Refer to MEL/MI-22-70 FMS Selector .*

  - One MFD
  - The relevant KCCU

    Note: *To comply with the minimum equipment requirements, it is sufficient for the KCCU to have either an operational Cursor Control Device (CCD), or an operational keyboard.*

  - One GPS receiver
    For associated MEL dispatch conditions, *Refer to MEL/DEL-34-ME1 GPS .*
  - One IRS
  - One FD engaged in the NAV mode.
    For associated MEL dispatch conditions, *Refer to MEL/MI-22-10 Flight Director .*

  Two RNAV systems may be required by the published approach chart.
- One FLS , if the flight crew intends to use the FLS function
- Flight plan data on both ND s.

BASIC RNP 0.3 APPROACH PROCEDURE

Refer to PRO-NOR-SOP-190-10-GINT Introduction .

KIND OF OPERATIONS

Applicable to: ALL

The airplane is certified in the public transport category (passengers and freight) for day and night operations, when the appropriate equipment and instruments required by the airworthiness and operating regulations are approved, installed, and in an operable condition. The airplane is certified in the following conditions:

- VFR and IFR
- Extended overwater flight
- Flight in icing conditions
- Maximum number of passenger seats: 853.

MINIMUM FLIGHT CREW

Applicable to: ALL

The minimum flight crew consists of 2 pilots.

GENERAL

Applicable to: ALL

AUTOPILOT

Minimum height for use of autopilot:

- At takeoff ..... 100 ft AGL, and at least 5 s after liftoff

L2 *An internal PRIM logic prevents the autopilot from engaging during 5 s after liftoff.*

L1
- Straight-in non-precision approach..... 200 ft AGL
- Circling approach..... 200 ft AGL
- ILS approach with CAT 1 displayed on FMA ..... 160 ft AGL
- After manual go-around..... 100 ft AGL
- All other phases..... 500 ft AGL

The use of AP or FD in OP DES or DES is not permitted, if the AFS CP selected altitude is set below MDA/MDH, or 500 ft AGL, whichever is the highest.

AUTOTHRUST

All AP/FD modes may be used with or without autothrust, except if specified.
Autothrust may be used with, or without AP/FD, in selected or managed speed/Mach.

FLIGHT MANAGEMENT

The FMS lateral and vertical navigation is approved for after takeoff, en route and terminal area operations and for instrument approach procedures and missed approach procedures.
The FMS lateral navigation (NAV mode) has been certified for instrument approach procedures except ILS, GLS, MLS, IGS, LOC, LOC-BC, LDA, and SDF.
The FLS (FMS Landing System) has been certified for instrument approach procedures except ILS, GLS, MLS, IGS, LDA, and SDF, using FMS navigation alone or FMS navigation associated with LOC, or ILS (GS out), or LOC-BC.
Approval of the FMS is based on the assumption that the navigation database has been validated for intended use. The airworthiness approval does not account for database accuracy or compatibility.
Obstacle clearance and adherence to airspace constraints remains a flight crew responsibility.
Fuel, time predictions/performance information is provided for advisory purpose only.
For instrument procedures not coded in the WGS 84 coordinate system, the GPS must be deselected, unless the shift between the local coordinate system and the WGS 84 is found acceptable for the intended operation.

Note: *1. The assessment of this shift can be done:*

- *in flight, monitoring the NAVAID raw data in non RNAV procedures,*
- *on ground performing a GPS survey of the procedure waypoints.*

2. RNAV (GPS) and RNP RNAV approach procedures require WGS 84 coordinates and GPS PRIMARY.

AIRWORTHINESS STANDARD COMPLIANCE

The FMS has been demonstrated to comply with applicable airworthiness requirements, including FAA AC 20–130A, for a navigation system integrating multiple navigation sensors, when operating with IRS, updated by radio or GPS.

The FMS also complies with the airworthiness part of:

- EASA AMC 20-4 (or JAA TGL 2 REV 1) for Basic RNAV
- JAA TGL 10 for Precision RNAV (compliance with paragraph 8.2 has not been demonstrated)
- FAA Advisory circular 20–129 for baro VNAV
- FAA Advisory circular 90–100 for terminal and en route RNAV operations
- FAA Order 8400.33 for RNP 4 in oceanic and remote area
- FAA Order 8400.12A for RNP 10 in oceanic and remote area
  RNP 10 oceanic/remote area operations are approved:
  - with GPS PRIMARY
  - without GPS PRIMARY (GPS deselected or inoperative), provided time limitations in IRS only navigation, acceptable to the operational authorities, are established.
- MASPS ED75A/DO236A, apart from vertical performance.

Note: *Compliance with the applicable airworthiness requirements does not constitute an operational approval.*

NAVIGATION PERFORMANCE

- **With GPS PRIMARY:**
  The FMS is certified in accordance with the lateral performance requirements of MASPS ED-75A/DO-236A for RNP operations.
  The RNP accuracy has been demonstrated to be:

	With AP ON - In NAV (all phases) - in F-LOC (approach phase)	With AP OFF and FD ON - In NAV (all phases) - In F-LOC (approach phase)	With AP OFF and FD OFF
En route	1 nm	1 nm	1.1 nm
Terminal area	0.5 nm	0.51 nm	0.51 nm
In approach	0.3 nm	0.3 nm	0.5 nm with F-LOC deviation. Not authorized without F-LOC deviation.

- **Without GPS primary:**
  The FMS is certified in accordance with the accuracy requirements and assumptions of MASPS ED-75A/DO-236A for RNP operations, provided the appropriate RNP value is checked or entered on the MFD and HIGH accuracy is displayed.
  Without GPS PRIMARY (GPS deselected or inoperative) the navigation accuracy is a function of ground radio navaid infrastructure or elapse time since last radio update.

Intentionally left blank

USE OF NAV MODE, AND FLS FUNCTION

Applicable to: ALL

USE OF NAV MODE

The NAV mode may be used (with V/S or FPA):

- In terminal area, when:
  - GPS PRIMARY is available, or
  - HIGH accuracy is displayed, and the appropriate RNP is checked, or entered on the MFD, or
  - Navaid raw data is monitored.
- In final approach:
  - For VOR, VOR/DME, or RNAV (including GPS) approach
  - But not for ILS, GLS, IGS, LOC, LOC B/C, LDA and SDF approaches.

USE OF FLS FUNCTION

The FLS function may be used:

- For an RNAV (including GPS) approach, when F-APP is displayed on FMA
- For VOR, or VOR/DME approach, when F-APP or F-APP + RAW capability is displayed on FMA
- For ILS G/S out, LOC only, or LOC B/C approach in association with LOC or LOC B/C modes, when FAPP or F-APP + RAW capability is displayed on FMA.

REQUIRED CONDITIONS FOR F-APP, F-APP + RAW, OR RAW ONLY CAPABILITY

Applicable to: ALL

The following table presents the FLS capability, as monitored by the FG , in accordance with required conditions:

L12

Required Conditions	FLS Capability		
	RAW ONLY	F-APP + RAW	F-APP
FMC	1	1	1
Navigation Accuracy (1)	No requirement	ACCURACY HIGH within one FMS	GPS PRIMARY within one FMS
FLS function (within MMR)	1	1	1
GPS receiver	0	0	1
Air Data Source	1 ADR	1 ADR	- 2 ADR s, or - 1 ADR , and 1 ISIS
IRS	1	1	2

(1) *If the NAV FM / GPS POS DISAGREE alert triggers, the FLS capability becomes RAW ONLY . For more information on the NAV FM / GPS POS DISAGREE , Refer to procedure .*

The Captain (First Officer) FMA displays the FLS capability, when the flight crew presses the Captain (First Officer) LS pb , and:

- The required conditions for F-APP , F-APP + RAW , or RAW ONLY capability are met
- An NPA has been selected on the FMS ARRIVAL page

L2 In addition, the NO FLS FOR THIS APPR message has not appeared on the MFD .

L1 - The FMS flight phase is descent or approach.

If the FLS capability downgrades, a triple click aural warning sounds.

MAXIMUM WIND CONDITIONS FOR AUTOMATIC APPROACH, LANDING, AND ROLL-OUT

Applicable to: ALL

The following limitations apply to automatic approach, or automatic landing and automatic roll-out of: GLS CAT I, ILS CAT II or ILS CAT III.

Maximum headwind..... 38 kt
Maximum tail wind..... 10 kt
Maximum cross wind..... 30 kt(CAT II/III 15 kt)

Note: Wind limitation is based on the surface wind reported by the tower. If the ND indicates a current wind speed that exceeds the above-noted autoland limitations, but the tower reports a surface wind speed within the limitations, then the flight crew can perform an automatic landing. If the tower reports a surface wind speed beyond the limitations, the flight crew can only perform a CAT I automatic approach without autoland.

AUTOMATIC APPROACH, LANDING, AND ROLL-OUT

Applicable to: ALL

GLS CATEGORY I

Minimum decision height..... 200 ft AGL

GLS CAT I WITHOUT AUTOLAND

At least one autopilot must be engaged in approach mode, and CAT 1 must be displayed on the FMA.
If the flight crew performs an automatic approach without autoland, the autopilot must be disengaged no later than 160 ft AGL.

GLS CAT I WITH AUTOLAND

At least one autopilot must be engaged in approach mode, and AUTO LAND must be displayed on the FMA.

ILS CATEGORY II

Minimum decision height..... 100 ft AGL
At least one autopilot must be engaged in approach mode, and CAT 2, CAT 3 SINGLE or CAT 3 DUAL must be displayed on the FMA.
If the flight crew performs an automatic approach without autoland, the autopilot must be disengaged no later than 80 ft AGL.

ILS CATEGORY III FAIL-PASSIVE

Minimum decision height..... 50 ft AGL
Alert Height (no DH)..... 100 ft AGL

If DH is not published for CAT III approach and the aircraft is fail passive automatic landing system, set Radio Altimeter Bug at 50ft RA as a CAT IIIa
At least one autopilot must be engaged in approach mode, and CAT 3 SINGLE or CAT 3 DUAL must be displayed on FMA.

ILS CATEGORY III FAIL-OPERATIONAL

The A/THR must be used in selected or managed speed.
Alert height..... 100 ft AGL
Minimum Runway Visual Range..... 75 m

CAT III WITH DH

Both APs must be engaged in approach mode and CAT 3 DUAL must be displayed on FMA.

CAT III WITHOUT DH

Both APs must be engaged in approach mode and CAT 3 DUAL must be displayed on FMA.

ENGINE OUT

ONE ENGINE INOPERATIVE

GLS CAT I autoland, ILS CAT II autoland, and ILS CAT III autoland are approved in CONF 3, and CONF FULL.

TWO ENGINES INOPERATIVE ON THE OPPOSITE SIDE

GLS CAT I autoland, and ILS CAT II autoland are approved in CONF 3.

AUTOMATIC LANDING

Applicable to: ALL

GLS CATEGORY I AUTOMATIC LANDING

GLS CAT I autoland is approved in CONF 3 and CONF FULL.

Automatic landing has been demonstrated:
- With GLS ground stations compliant with ICAO annex 10 amendment 76 and 77.
- With a GLS glideslope angle inside a range of -2.5 ° and -3.5 °
- For airport altitude between -1 000 ft and 9 200 ft
- For weights between 305 t , and maximum landing weight
- At approach speed equal to VLS + wind correction, with a minimum wind correction of 5 kt, and a maximum wind correction of 15 kt.

The performance of ROLL OUT mode has been demonstrated on dry and wet runways. But the performance on snow covered, or icy runway has not been demonstrated.

Note: Depending on the situation (e.g. emergency or other) and provided that the runway is approved for automatic landing, the flight crew can decide to perform an autoland up to the maximum takeoff weight.

ILS CATEGORY II OR ILS CATEGORY III AUTOMATIC LANDING

CAT II and CAT III autoland is approved in CONF 3 and CONF FULL.

Automatic landing has been demonstrated:
- On CAT II and CAT III ILS beam with an ILS glideslope angle inside a range of -2.5 ° and -3.5 °
- For airport altitude between -1 000 ft and 9 200 ft
- For weights between 672 410 lb , and maximum landing weight
- At approach speed equal to VLS + wind correction, with a minimum wind correction of 5 kt, and a maximum wind correction of 15 kt.

The performance of ROLL OUT mode has been demonstrated on dry and wet runways. But the performance on snow covered, or icy runway has not been demonstrated.

Automatic landing system performance has been demonstrated on CAT II and CAT III ILS beams. However, automatic landing in CAT I, or better weather conditions is possible on CAT I ground installation, or on CAT II/III ground installations when ILS-sensitive areas are not protected, if the following precautions are taken:
- The airline has checked that the ILS beam quality, and the effect of the terrain profile before the runway have no adverse effect on autopilot guidance. In particular, the effect of terrain discontinuities within 984 ft before the runway threshold must be evaluated.
- The flight crew is aware that LOC or G/S beam fluctuations, independent of the aircraft system, may occur. The PF is prepared to immediately disconnect the autopilot, and to take the appropriate action, should unsatisfactory guidance occur.
- At least CAT 2 capability is displayed on the FMA and CAT II/III procedures are used.
- Visual references are obtained, at a DH appropriate for the CAT I approach being flown, or a go-around is performed.

Note: Depending on the situation (e.g. emergency or other) and provided that the runway is approved for automatic landing, the flight crew can decide to perform an autoland up to the maximum takeoff weight.

APPROACH CAPABILITY

Applicable to: ALL
Impacted by TDU: 00021981 Approach Capability

The FG computes its own approach capability: CAT1, CAT2, CAT3 SINGLE, or CAT3 DUAL, and displays the approach capability on the FMA. Each capability depends on the availability of

aircraft systems and functions. When the approach capability downgrades, a triple click aural warning sounds.

FAIL-OPERATIONAL AUTOMATIC LANDING SYSTEM

An automatic landing system is fail-operational if, in the event of a failure below alert height, the remaining part of the automatic system allows the aircraft to complete the approach, flare, and landing. A CAT3 DUAL system is a fail-operational automatic landing system.

Note: In the event of a failure, the automatic landing system operates as a fail-passive system.

FAIL-PASSIVE AUTOMATIC LANDING SYSTEM

An automatic landing system is fail-passive if, in the event of a failure, there is no significant out-of-trim condition, or deviation of flight path or attitude, but the landing is not completed automatically. A CAT3 SINGLE system is a fail-passive automatic landing system.

Note: With a fail-passive automatic landing system, the flight crew controls of the aircraft after a failure.

ALERT HEIGHT

The alert height is the height above the runway, above which a CAT3 autoland would be discontinued, and a missed approach executed, if a failure occurred in either the airplane systems, or the relevant ground equipments. Below the alert height, if such a failure occurs, the flare, touchdown and roll-out may be accomplished using the remaining automatic system.

Note: Below 200 ft RA, the FG freezes the CAT3 capability. Therefore, a failure occurring below 200 ft RA does not change the capability of the system.

APPROACH CAPABILITY

Applicable to: ALL
Impacted DU: 00018781 Approach Capability

The FG computes its own approach capability: CAT1, CAT2, CAT3 SINGLE, or CAT3 DUAL, and displays the approach capability on the FMA. Each capability depends on the availability of aircraft systems and functions. When the approach capability downgrades, a triple click aural warning sounds.

FAIL-OPERATIONAL AUTOMATIC LANDING SYSTEM

An automatic landing system is fail-operational if, in the event of a failure below alert height, the remaining part of the automatic system allows the aircraft to complete the approach, flare, and landing. A CAT3 DUAL system is a fail-operational automatic landing system.

Note: In the event of a failure, the automatic landing system operates as a fail-passive system.

FAIL-PASSIVE AUTOMATIC LANDING SYSTEM

An automatic landing system is fail-passive if, in the event of a failure, there is no significant out-of-trim condition, or deviation of flight path or attitude, but the landing is not completed automatically. A CAT3 SINGLE system is a fail-passive automatic landing system.

Note: With a fail-passive automatic landing system, the flight crew controls of the aircraft after a failure.

ALERT HEIGHT

The alert height is the height above the runway, above which a CAT3 autoland would be discontinued, and a missed approach executed, if a failure occurred in either the airplane systems, or the relevant ground equipments. Below the alert height, if such a failure occurs, the flare, touchdown and roll-out may be accomplished using the remaining automatic system.

Note: Below 200 ft RA, the FG freezes the CAT3 capability, except:
- *If the AC busbars are not supplied by 4 different generators, or*
- *If each DC busbar is not supplied by its assigned TR.*

Therefore, except for these cases, a failure occurring below 200 ft RA does not change the capability of the system displayed on the FMA.

GROUND/RUNWAY EQUIPMENT REQUIRED FOR PRECISION INSTRUMENT APPROACHES

Applicable to: ALL

1
2

Component	CAT I (1)	CAT II	CAT III
LOCALIZER/GLIDESLOPE	Yes	Yes	Yes
Outer Marker	Yes (7)	Yes (7)	Yes (7)
Middle Marker	No (2)	No (2)	No
Inner Marker	No	Yes (7)	Yes (7)
Approach Light System (ALS)	Yes (3)	Yes (3)	Yes (3)
Sequenced Flashing Lights (SFL; also part of RAIL, ALSF, etc.)	Yes (4)	Yes (6)	No
High Intensity Runway Lights	Yes	Yes	Yes

Continued on the following page

Continued from the previous page

Component	CAT I (1)	CAT II	CAT III
Touchdown Zone Lights (TDZ)	Yes (5)	Yes (6)	Yes
Runway Centerline Lights (CL)	Yes (5)	Yes (6)	Yes

(1) CAT I ILS approaches may be flown with equipment outages (e.g. CL out) if the approach chart gives specific minima to be used with such outages.

(2) For countries that impose higher minima for MM OUT condition, refer to Airway Manual

(3) CAT I ILS approaches in visibilities of 1,200M (4,000 ft) RVR or 3/4 mile (or better) however, do not require ALS. All CAT II approaches and CAT III approaches require "standard" ALS (e.g. ALSF-1, ALSF-2) or equivalent international system. (e.g. HIALS)

(4) CAT I ILS approaches in visibilities of RVR 1,200M (4,000 ft) or 3/4 mile (or better) however, do not require SFL.

(5) If TDZ and/or CL inoperative, refer to FOM chapter 4 Weather(CAT I Minima by Lighting Facilities).

(6) CATII approach operation can be authorized at the airports with reduced lighting facilities those have been approved by Ops Specs. Refer to the Terminal Chapter (Green Page) of the Airway Manual for approved runways (e.g. ANC 07L).

(7) A marker is considered out of service only when none of the authorized substitutes is available. These include the following and, except for ASR and PAR, are shown on the approach chart.

Authorized Substitute	Outer Marker	Middle Marker	Inner Marker
COMPASS LOCATOR 1)	Yes	Yes	No
NDB, VOR, DME fix, Minimum GSIA Fix or ASR Radar Fix 2)	Yes	No	No
PAR Radar Fix 2)	Yes	Yes	No
Radio Altimeter	No	No	Yes 3)

1) If locators are used for both the outer and middle marker, dual ADF or single ADF with a dual tuning head is required.
2) Where available and if requested by the flight crew
3) Where applicable : e.g., at some CAT II installations radio altimeter is not authorized to identify decision height, and this is specified on the approach chart. (e.g. "RA NA")

REQUIRED EQUIPMENT FOR CAT II, OR CAT III OPERATION

Applicable to: ALL

In order to perform a CAT II or CAT III operation, the flight crew must check that the aircraft has the appropriate capability. The FG monitors one part of the required equipment (See Required Equipment Monitored by the FG), and computes the approach capability. The other part of the required equipment is not monitored by the FG : See Required Equipment not Monitored by the FG .

Any approach capability downgrade, computed by the FG , is announced by:
- A triple click aural warning
- The display of the inoperative capability on the SD STATUS page.

The loss of a required equipment, monitored by the FG , is announced by an assigned alert (e.g. F/CTL FCDC 1 FAULT), or by the AUTO FLT APPROACH CAPABILITY DOWNGRADED alert (*Refer to procedure*).

The occurrence of a failure or a warning in approach may modify the approach procedure. For more information, *Refer to Failures or warnings during a CAT II or CAT III approach* .

REQUIRED EQUIPMENT MONITORED BY THE FG

The following table presents the equipment, as monitored by the FG , required to perform CAT II, or CAT III approach, and landing:

L123

Required Equipment Monitored by FG	Precision Approach Capability		
	CAT2	CAT3 SINGLE	CAT3 DUAL
AP	1 AP engaged	1 AP engaged	2 AP s engaged
A/THR	Not required	Active	Active
PRIM	1	1	- PRIM 1 and PRIM 2, or - PRIM 1 and PRIM 3.
SEC	1	1	1
Flight control vertical accelerometer, used for the computation of pitch normal law *(1)*	3	3	4
Flight control gyrometer, used by flight controls *(1)*	5	5	6
Slat Control Unit	1	1	2
Flap Control Unit	1	1	2

Normal law	Available	Available	Available
Hydraulic circuit	1	1	2
AFS CP , or CAPT AFS CP backup, or F/O AFS CP backup	1	1	1
PFD display *(1)*	2	2	2
FWS , including the audio function	1	1	2
FCDC	1	1	2
Normal or alternate braking	Not required	Not required	Available
Antiskid	Not required	Not required	Available
Nosewheel Steering *(2)*	Not required	Not required	Available
LGERS	1	1	1
Ground spoilers	Available	Available	Available
Radio Altimeter	1	2	2

Continued on the following page

Continued from the previous page

Required Equipment Monitored by FG	Precision Approach Capability		
	CAT2	CAT3 SINGLE	CAT3 DUAL
ILS receiver (3)	2	2	2
ADR	2	2	3
IRS in NAV mode (1) (4)	2	2	3
Angle of Attack (1)	2	2	3
Sideslip angle (1)	2	2	3
Engine	1 on the right side, and 1 on the left side	3	- 4, or - 3, with the APU running, and one APU generator is connected to the electrical network. (5)
AC busbar	(6)	(6)	6
Supply of AC busbars	(6)	(6)	4 different generators supply the AC busbars
Supply of DC busbars	(6)	(6)	Each DC busbar is supplied by its assigned TR

(1) The PRIM s monitor this equipment, and may trigger the AUTO FLT APPROACH CAPABILITY DOWNGRADED alert. For more information, Refer to Procedure .

(2) In CAT3 DUAL , the nosewheel steering must be able to receive AP guidance orders.

If the communication between the nosewheel steering and the FG is failed:
- *CAT3 DUAL is lost*
- *The AUTO FLT ROLL OUT FAULT alert triggers.*

(3) In addition, the tuning of both ILS receivers must be consistent.
If the tuning of both ILS receivers is not consistent, the NAV LS TUNING DISAGREE alert triggers.

(4) CAT3 DUAL will not be available, if the flight crew has set the ATT HDG selector out of NORM.

(5) If one engine fails, only three generators supply the AC busbars, and so CAT3 DUAL is lost. However, if the flight crew starts the APU , CAT3 DUAL is recovered.

(6) In accordance with the failure, and the associated equipment loss, capability downgrade may occur.

The FMA s display the precision approach capability:
- In accordance with the minimum required equipment, and
- When all of the following conditions are met:
  - An ILS approach has been selected on the FMS ARRIVAL page
  - The North reference is MAG
  - The LOC and G/S modes are armed, or engaged.

L2 CAT3 SINGLE , or CAT3 DUAL is memorized at 200 ft RA , and remains displayed as long as:
- At least one AP is engaged, and
- LAND , FLARE , or ROLL OUT is engaged.

L1 **REQUIRED EQUIPMENT NOT MONITORED BY THE FG**

The following table presents the equipment, not monitored by the FG , required to perform CAT II or CAT III approach, and landing:

Required Equipment Not Monitored by FG	Precision Approach Capability		
	CAT2	CAT3 SINGLE	CAT3 DUAL
AP pb , or CAPT sidestick pushbutton, or F/O sidestick pushbutton	2	2	2
Autoland light	1	1	1
AP OFF alert	Available	Available	Available
DH Indication	1 for F/O	1 for F/O	1 for F/O
Attitude indicationon PFD	2	2	2
Attitude indication on standby instrument	1	1	1
Windshield wiper	1 for CAPT	1 for CAPT	1 for CAPT
Windshield heating	1 for CAPT	1 for CAPT	1 for CAPT

To perform an automatic roll-out in CAT2 , or CAT3 SINGLE , the antiskid, the nosewheel steering, and the normal or alternate braking must be available.

REQUIRED EQUIPMENT FOR GLS CAT I AUTOMATIC APPROACH AND AUTOMATIC LANDING

Applicable to: ALL

In order to perform a GLS CAT I automatic approach and automatic landing, the flight crew must check that the aircraft has the appropriate capability. The FG monitors a part of the required equipment (See Required Equipment Monitored by the FG), and computes the approach capability. The other part of the required equipment is not monitored by the FG : See Required Equipment not Monitored by the FG .

Any approach capability downgrade, computed by the FG , is announced by:
- A triple click aural warning
- The display of the inoperative capability on the STATUS SD page.

The loss of a required equipment, monitored by the FG , is announced by an assigned alert (e.g. F/CTL FCDC 1+2 FAULT), or by the AUTO FLT APPROACH CAPABILITY DOWNGRADED alert (*Refer to procedure*).

REQUIRED EQUIPMENT MONITORED BY THE FG

The following table presents the equipment, as monitored by the FG , required to perform a GLS CAT I automatic approach and automatic landing:

L123

Required Equipment Monitored by FG	Precision Approach Capability GLS AUTO LAND
AP	1 AP engaged
A/THR	Not required
PRIM	1
SEC	1
Flight control vertical accelerometer, used for the computation of pitch normal law (1)	3
Flight control gyrometer, used by flight controls (1)	5
Slat Control Unit	1
Flap Control Unit	1
Rudder trim	Available

Angle of Attack (1)	2
Sideslip angle (1)	2
Engine	1 on the right side, and 1 on the left side
AC busbar	(3)

Continued on the following page

Continued from the previous page

Required Equipment Monitored by FG	Precision Approach Capability GLS AUTO LAND
Supply of AC busbars	(3)
Supply of DC busbars	(3)

(1) *The PRIM s monitor this equipment, and may trigger the AUTO FLT APPROACH CAPABILITY DOWNGRADED alert. For more information, Refer to Procedure .*

(2) *In addition, the tuning of both GLS receivers must be consistent.*
If the tuning of both GLS receivers is not consistent, the NAV LS TUNING DISAGREE alert triggers.

(3) *In accordance with the failure, and the associated equipment loss, capability downgrade may occur.*

The FMA s display the GLS capability:
- In accordance with the minimum required equipment, and
- When all of the following conditions are met:
  - A GLS approach is selected on the FMS ARRIVAL page
  - The North reference is MAG
  - The LOC and G/S modes are armed, or engaged.

REQUIRED EQUIPMENT NOT MONITORED BY THE FG

The following table presents the equipment, not monitored by the FG , required to perform a GLS CAT I automatic approach, and automatic landing:

Required Equipment Not Monitored by FG	Precision Approach Capability GLS AUTO LAND
Normal or alternate braking	(1)
Antiskid	(1)
Nosewheel steering	(1)
AP pb , or CAPT sidestick pushbutton, or F/O sidestick pushbutton	2
Autoland light	1
AP OFF alert	Available
DH Indication	1 for PM
Attitude indication on PFD	2
Attitude indication on standby instrument	1
Windshield wiper	1 for PF
Windshield heating	1 for PF

(1) *To perform an automatic roll-out in GLS CAT I, the antiskid, the nosewheel steering, and the normal or alternate braking must be available.*

FUEL

Intentionally left blank

LIM-28-PLP PRELIMINARY PAGES

TABLE OF CONTENTS

Certified fuel....A
Maximum allowed wing fuel imbalance....B
Fuel Temperature....C

Intentionally left blank

CERTIFIED FUEL

Applicable to: ALL

The fuel system has been certified for the following fuels:

- JET A
- JET A1
- JP5
- JP8
- RT
- TS-1
- N°3 Jet Fuel (RP-3).

MAXIMUM ALLOWED WING FUEL IMBALANCE

Applicable to: ALL

Maximum Allowed Wing Imbalance at Takeoff, in Flight , and Landing	
Feed tanks 1 / Feed tanks 4	6 613 lb
Feed tank 2 / Feed tank 3	6 613 lb
Left inner tank / Right inner tank	6 613 lb
Left mid tank / Right mid tank	5 511 lb
Left outer tank / Right outer tank	2 645 lb

Note: In exceptional conditions (i.e. fuel system failures) the above-mentioned maximum fuel imbalance values may be exceeded without significantly affecting the aircraft handling qualities. The aircraft remains fully controllable in all phases of the flight.

FUEL TEMPERATURE

Applicable to: ALL

MINIMUM FUEL TEMPERATURE

The minimum fuel temperature is the actual freezing point of the fuel used for the flight.
If the actual freezing point of the fuel used for the flight is unknown, use the following fuel specification freezing point.

JET A	JET A1	JP5	JP8	RT	TS-1	RP-3
-40 °C	-47 °C	-46 °C	-47 °C	-50 °C	-50 °C	-47 °C

MAXIMUM FUEL TEMPERATURE

The maximum fuel temperature is +53 °C.

FUEL MIXABILITY

The various types of fuel can be mixed in all proportions.

The freezing point of a fuel mixture varies, based on non-linear laws. Therefore, the only reliable way to obtain an accurate freezing point of a mixture of fuels is to measure the freeze point.

If this is not possible, the freezing point of the mixture in one tank should be:

- The highest freezing point, if the fuel type with the lowest quantity is more than 10 % of the mixture, or
- The freezing point of the fuel type with the highest quantity, if the fuel type with the lowest quantity is less than 10 % of the mixture.

For example, assuming that the aircraft has a mixture of fuel type JET A and fuel type JP8, and that the freezing points are in accordance with the specifications:

- If there is less than 10 % of fuel type JET A, the freezing point of the mixture can be considered as that of fuel type JP8: -47 °C (i.e. the fuel type with the highest quantity)
- If there is more than 10 % of fuel type JET A, the freezing point of the mixture can be considered as that of fuel type JET A: -40 °C (i.e. the highest freezing point).

TABLE OF CONTENTS

HUD.....A

Intentionally left blank

HUD

Applicable to: ALL

The use of the Head-Up Display (HUD) is approved for all phases of flight with the following limitations:

MANUAL APPROACH

The flight crew may use the HUD for visual, or instrument CAT I approaches, provided that the selected slope is between -2 ° and -4 °.

AUTOMATIC APPROACH, LANDING AND ROLL OUT

The flight crew may use the HUD to monitor automatic approach, landing and roll out.

Note: Following automatic approach and landing, the HUD is approved as a reversionary means for roll out in the event of untimely autopilot disconnection or failure of a system affecting the automatic roll out.

SYNTHETIC RUNWAY

The flight crew must not use the synthetic runway for runway identification.

Note:
- *The HUD displays a synthetic runway during the approach phase, if the heading of the aircraft is ±80 ° of the runway QFU, in order to help the flight crew locate the runway*
- *During a precision approach, the synthetic runway and the LOC axis on the HUD may not overlay the real runway*
- *In Non-Precision Approaches (NPA), the synthetic runway course may be different from the real runway course by a few degrees.*

Intentionally left blank

ROW - ROP

Applicable to: ALL

Runway Overrun Warning - Runway Overrun Protection are approved:
- For dry and wet runway only
- With thrust reverser available
- Without any alert that impacts landing performance.

Note: *In the case of alert that impacts landing performance, ROW-ROP alerts are available. The ROW-ROP alerts are based on landing performance that does not take into account the performance penalties linked to the alert that impact the landing performance.*

BTV

Applicable to: ALL
Impacted DU: 00021915 BTV

CAUTION	BTV must be used only on dry and wet runway. The use of BTV is prohibited on contaminated runway. The use of BTV is prohibited on the runways 13 R or 13 L associated with the approach VOR or GPS 13R or 13 L "CANARSIE" at JFK airport.

Note: *Precision on runway condition:*
- *Any runway declared damp must be considered wet*
- *Any wet runway including a PFC or grooved surface must be considered wet*
- *Any wet runway declared as slippery when wet must be considered contaminated.*

BTV can be used every time at landing, independently of wind condition, visibility, aircraft configuration (e.g. weight, CG, landing configuration), manual landing, automatic landing.
The flight crew should not use BTV if the airport destination is not available in the airport navigation database.

BTV

Applicable to: ALL
Impacted by TDU: 00024053 BTV

CAUTION	BTV must be used only on dry and wet runway. The use of BTV is prohibited on contaminated runway.

Note: *Precision on runway condition:*
- *Any runway declared damp must be considered wet*
- *Any wet runway including a PFC or grooved surface must be considered wet*
- *Any wet runway declared as slippery when wet must be considered contaminated.*

BTV can be used every time at landing, independently of wind condition, visibility, aircraft configuration (e.g. weight, CG, landing configuration), manual landing, automatic landing.
The flight crew should not use BTV if the airport destination is not available in the airport navigation database.
BTV cannot be used in the case of ECAM alert that impact the landing performance.

BRAKING SYSTEM

Applicable to: ALL

Maximum brake temperature for takeoff..... 300 °C
The braking system is not designed to hold the aircraft in a stationary position when a high thrust level is applied on at least one engine. During ground procedures that require a thrust increase with braking, the flight crew must ensure that the aircraft remains stationary.

TABLE OF CONTENTS

Minimum Flight Crew Oxygen Pressure.....A
Minimum Cabin Oxygen Pressure.....B

Intentionally left blank

MINIMUM FLIGHT CREW OXYGEN PRESSURE

Applicable to: ALL

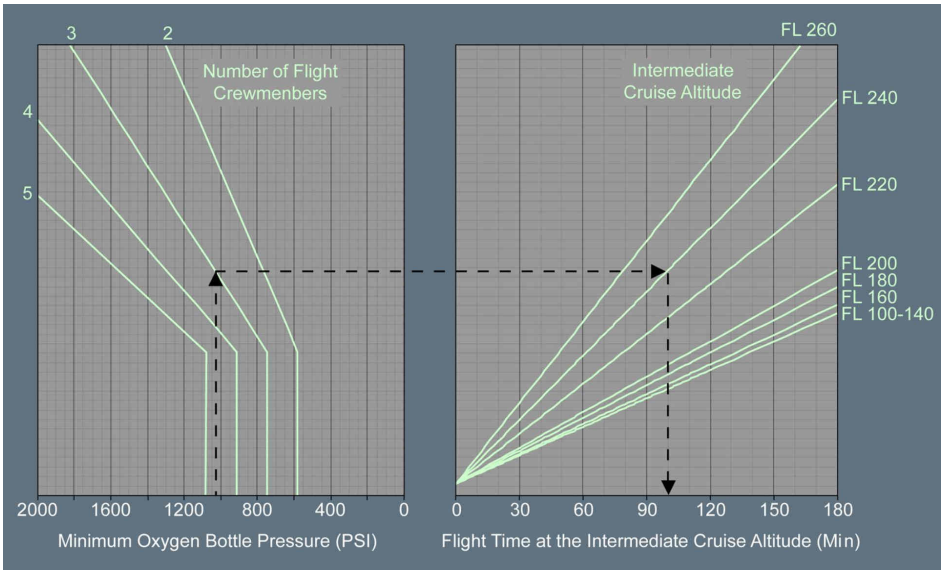
The minimum oxygen bottle pressure, indicated on the graph, takes into account all of the following:

1.	The preflight checks for all flight crewmembers.	
2.	Only one flight crewmember is in the cockpit, and uses the oxygen mask at 8 000 ft of cabin altitude for 15 min , with the N/100% selector set to N. This can occur two times.	
3.	The most demanding case among the two following: *(1)*	Protection after loss of cabin pressure for all flight crewmembers, with the N/100% selector set to N, to fly: - 1 min at FL 430 - Descent from FL 430 to an intermediate cruise altitude at 5 500 ft/min The intermediate cruise altitude is read on the following graph. - Flight time at the intermediate cruise altitude The flight time is read on the graph. - Descent from the intermediate cruise altitude to FL 100 at 5 500 ft/min .
		Protection against toxic gases and smoke for all flight crewmembers with the N/100% selector set to 100%, at 8 000 ft of cabin altitude for 15 min .
4.	One flight crewmember uses the oxygen mask when the aircraft: - Takes off from an airport at, or above 9 200 ft , or - Lands on an airport at, or above 9 200 ft . For information on the use of the mask during high altitude airport operation, *Refer to PRO-SPO-HAO High Altitude Airport Operation* .	
5.	Normal system leakage.	
6.	Not usable quantity.	

(1) *In accordance with FAR 121.333, the fixed oxygen for the cockpit must provide enough oxygen to protect all flight crewmembers, with the N/100% selector set to N, after loss of cabin pressure, to fly:*
- *A descent from FL 430 to FL 100 , with a constant descent rate, for 10 min*
- *A step at FL 100 for 110 min .*

However, this profile is less demanding than the two cases.

Minimum Oxygen Bottle Pressure



Note: 1. *The values of the oxygen bottle pressure refers to the oxygen bottle pressure displayed on the DOOR SD page.*
2. *The above conditions are based on the use of a sealed mask on a non-bearded face. They may be affected when the masks are used by bearded flight crewmembers.*
3. *It is recommended to fly at, or close to the profile when the altitude is above FL 250 . If the aircraft flies below the profile, and above FL 250 , the oxygen consumption will be higher than flying the profile.*

FLIGHT ABOVE FL 410

For FAA -certified aircraft, and in accordance with FAR 121.333, if flight above FL 410 is expected:

- Before departure, the flight crew must increase the minimum oxygen bottle pressure. The amount of the increase is based on the amount of time that the aircraft will be above FL 410 . For calculation purposes, the minimum oxygen bottle pressure must be increased by 73 PSI per hour.
- When the aircraft goes above FL 410 , one flight crewmember must don the oxygen mask, and set the N/100% selector to N.

MINIMUM CABIN OXYGEN PRESSURE

Applicable to: ALL

MINIMUM OXYGEN BOTTLE PRESSURE

In the case of depressurization, the fixed oxygen system for the cabin provides oxygen to the cabin (passengers and cabin crew), and to the crew rest compartments via individual oxygen masks.

The fixed oxygen system has the capacity to provide the necessary amount of oxygen:

- To the number of masks to be used by the cabin occupants
  The cabin occupants include the passengers, and the cabin crew.
- To fly on, or below one of the three following profiles:
  - See Descent from FL 430 to FL 150 in 10 min, or
  - See Emergency descent , or
  - See Emergency descent with a step flight level.
- When the oxygen bottle pressure, indicated on the DOOR SD, is above the minimum bottle pressure, indicated on one of the following table, or graph.

DESCENT FROM FL 430 TO FL 150 IN 10 MIN

Note: This profile is required by JAR OPS 1.770.

The following table indicates the minimum oxygen pressure necessary to provide oxygen:

- To the number of cabin masks in use
- During a descent from FL 430 to FL 150 in 10 min, with a constant descent rate.

Number of Cabin Masks in Use	100	200	300	400	500	600	700	800
Minimum Oxygen Bottle Pressure PSI	407	706	999	1290	1579	More than 1 850 PSI is necessary.		

EMERGENCY DESCENT

The following table indicates the minimum oxygen pressure necessary to provide oxygen:

- To the number of cabin masks in use
- For the following profile:
  - 1 min at FL 430
  - An emergency descent from FL 430 to FL 100, with a descent rate of 5 500 ft/min.
- In the case of depressurization.

Number of Cabin Masks in Use	100	200	300	400	500	600	700	800
Minimum Oxygen Bottle Pressure PSI	286	469	649	827	1003	1178	1352	1526

EMERGENCY DESCENT WITH A STEP FLIGHT LEVEL

The following graph indicates the minimum oxygen bottle pressure necessary to provide oxygen:

- To the number of cabin masks in use
- For the following profile:
  - 1 min at FL 430
  - Descent from FL 430 to an intermediate cruise altitude at 5 500 ft/min
    The intermediate cruise altitude is read on the graph.
  - Flight time at the intermediate cruise altitude
    The flight time is read on the graph.
  - Descent from the intermediate cruise altitude to FL 100 at 5 500 ft/min.
- In the case of depressurization.

Minimum Oxygen Bottle Pressure for Emergency Descent with a Step Flight Level

PrinterS....C

Intentionally left blank

OIS - ONBOARD INFORMATION SYSTEM

Applicable to: ALL

FLT OPS SIDE

FLT OPS STS PAGE

- The FLT OPS STS page does not display the navigation charts validity after the flight crew member has started the laptop
- When the connection of a laptop to the network is lost then recovered, the synchronization of the FLT OPS STS page is partially lost between the CAPT and the F/O laptop
- The OIS version may not appear on the FLT OPS STS page.

For more information, *Refer to DSC-46-20-10-30 FLT OPS STS Page* .

LOAD BOX/EXPORT BOX

- The flight crew must not use two USB devices at the same time on the same laptop
- If the flight crew plugs a USB device when the LOAD BOX is already open, the list of data to load is not automatically refreshed.

For more information, *Refer to DSC-46-20-10-30 LOAD BOX / EXPORT BOX* .

OPS LIBRARY

- The OPS LIBRARY may take several minutes to start, when the flight crew starts the application for the first time.
  When the application starts, "NOT AVAILABLE" may be temporarily displayed on the OIT .
- When the flight crew opens a manual or performs an ECAM search, the first documentary unit that the flight crew has selected may not appear, *Refer to DSC-46-20-50-10 How to Start the OPS LIBRARY* and *Refer to DSC-46-20-50-10 How to Use ECAM Search* .
- There is no indication to the flight crew when the push/receive function of MEL / CDL items from the elogbook application to the FLT OPS side is lost, *Refer to DSC-46-20-50-10 How to use The Logbook Status* .

FLT FOLDER

- The flight crew must close the FLT FOLDER application before exiting the session
- The performance applications are not available after the FLT FOLDER closure
- When the flight crew starts the export process, if the SATCOM is the only communication means available, the export process may be blocked, because the data file size is bigger than the size permitted by the SATCOM, *Refer to DSC-46-20-50-30-40 Send the EFF to the Ground via Wireless* .

NSS AVNCS SIDE

ELOGBOOK

- The flight crew must not use the technical logbook application during a synchronization process, *Refer to DSC-46-20-50-40 How to Accept the Aircraft* and *Refer to DSC-46-20-50-40 How to Close the Flight* .

AIRLINE OPERATIONAL CONTROL (AOC)

- On the FLT OPS side, when an AOC notification is selected on the Captain's (F/O 's) OIT , the corresponding notification is not deleted on the other OIT . The notification must be manually deleted
- A customized notification is pushed to the FLT OPS side and appears on one OIT when the flight crewmember selects the FLT OPS side, only if this OIT s display the NSS AVNCS side when the notification occurs
- The COMPANY COM application may temporarily freeze after navigation through the application. If the freeze persists, the flight crew should restart the laptop.

PEA - PERFORMANCE APPLICATIONS

Applicable to: ALL

TAKEOFF

INOPERATIVE FLEX AND DERATED TAKEOFF MODE

In the case of a MEL item that forbids the use of FLEX or Derated Takeoff thrust, the FLEX and the Derate Level THRUST options are still available in T.O PERF, even though it is forbidden by the associated MEL procedure.
Workaround: Select the TOGA THRUST option.

For more information about this limitation:
- *Refer to PER-TOF-TOC-ACS-THR Inoperative FLEX and Derated Takeoff Mode*
- *Refer to PER-TOF-TOC-ACM-THR Inoperative FLEX and Derated Takeoff Mode*
- *Refer to PER-TOF-TOC-AFS-MEL Inoperative FLEX and Derated Takeoff Mode* .

MULTIPLE RESULTS

The TOGA result line is sometimes overlapped by the FLEX result line.
Workaround: Move the cursor over the first line of the result table and select it.
For more information about this limitation, *Refer to PER-TOF-TOR-MRS FLEX Takeoff* .

ENG. A-ICE VALVE POSITION

Calculation may fail when the MEL item "Eng. A-Ice valve position: Stuck open" is selected.

Workaround:
- Deselect the MEL item "Eng. A-Ice valve position: Stuck open"
- Select "Engine & Wing" in the A-ICE drop down list of the CONDITIONS panel.

This procedure provides the correct results.
For more information about this limitation, *Refer to PER-TOF-TOC-AFS-MEL Eng. A-Ice Valve Position* .

TAKEOFF WEIGHT

TOW in Tons

For some calculation sequences with at least two computations, when the flight crew enters the TOW in Tons, T.O PERF may use a lower TOW value.
Workaround: Enter the TOW value directly in Kilograms.

For more information about this limitation:
- *Refer to PER-TOF-TOC-ACS Takeoff Weight*
- *Refer to PER-TOF-TOC-ACM Takeoff Weight* .

Different rounding between LOADSHEET and T.O PERF

When the flight crew has run a LOADSHEET computation and then switches to T.O PERF, the TOW value is retrieved from the LOADSHEET results. There is a different rounding between LOADSHEET and T.O PERF: the TOW may be different by 100 kg . The TOW in T.O PERF is rounded up to the next 100 kg .

For more information about this limitation:
- *Refer to PER-TOF-TOC-ACS Takeoff Weight*
- *Refer to PER-TOF-TOC-ACM Takeoff Weight* .

Switch between T.O PERF and LOADSHEET while a T.O PERF computation is running

When the flight crew switches between T.O PERF and LOADSHEET while a T.O PERF computation is running, the T.O PERF RESULTS panel may display results for a weight different from the one displayed on the CONDITIONS and RESULTS panels.
Workaround: Do not switch from T.O PERF to LOADSHEET while a T.O PERF calculation is running.

For more information about this limitation:
- *Refer to PER-TOF-TOC-ACS Takeoff Weight*
- *Refer to PER-TOF-TOC-ACM Takeoff Weight* .

CDL

When a CDL item is selected, the number of missing items is hidden in the ACFT STS box.
Workaround: Use the scroll bar to display the hidden information.

For more information about this limitation, *Refer to PER-TOF-TOC-AFS CDL* .

SYNCHRONIZATION WITH LOGBOOK

If the Logbook status is lost in the FLT OPS domain, T.O PERF may synchronize with an old Logbook status.
For more information about this limitation, *Refer to PER-TOF-TOC-AFS Synchronization with Logbook* .

FULL RUNWAY MODIFICATION: T.O SHIFT

In MODIFY RWY - Full Mode, the T.O SHIFT value is hidden on the AIRPORT panel, but there is no impact on the computation. T.O PERF uses the relevant T.O SHIFT value and displays this value on the RESULTS panel.

For more information about this limitation:
- *Refer to PER-TOF-TOC-RWY SINGLE RWY COMPUTATION Panel - Length-CWY-SWY*
- *Refer to PER-TOF-TOC-RWY SINGLE RWY COMPUTATION Panel - TORA-TODA-ASDA* .

REDUCED RUNWAY MODIFICATION

Entry Angle

In MODIFY RWY - Reduced Mode, the ENTRY ANGLE value is not correctly displayed on the AIRPORT panel, but there is no impact on the calculation. The T.O PERF application uses the relevant entry angle value.

In MODIFY RWY - Reduced Mode, the following equivalences apply:
- 0 on the AIRPORT panel corresponds to 0 °
- 1 on the AIRPORT panel corresponds to 90 °
- 2 on the AIRPORT panel corresponds to 180 °
- 3 on the AIRPORT panel corresponds to 180 ° pad
- 4 on the AIRPORT panel corresponds to an entry angle value customized by the airline.

For more information about this limitation:
- *Refer to PER-TOF-TOC-RWY SINGLE RWY COMPUTATION Panel - Length-CWY-SWY*
- *Refer to PER-TOF-TOC-RWY SINGLE RWY COMPUTATION Panel - TORA-TODA-ASDA* .

Additional Obstacle

When the flight crew adds one obstacle from RWY end by using the ADD 1 OBSTACLE function, the label “Distance: 0(m) from RWY start” appears on the VIEW OBST subpanel. There is no impact on the computation. T.O PERF uses the relevant obstacle longitudinal distance from RWY start.
For more information about this limitation, *Refer to PER-TOF-TOC-RWY-CRR VIEW OBST* .

MULTIPLE RUNWAY COMPUTATION (LENGTH-CWY-SWY)

The label "TORA" is displayed instead of the label "LENGTH" on the MULTIPLE RWY COMPUTATION panel.
For more information about this limitation, *Refer to PER-TOF-TOC-RWY MULTIPLE RWY COMPUTATION Panel - Length-CWY-SWY* .

LANDING

ECAM ALERTS AND AUTOLAND

The selection of an ECAM alerts item plus the LDG TECHNIQUE Autoland is not possible even if the associated ECAM alert enables the use of Autoland system. The following error message appears: "Computation using autoland with ECAM Alert is not possible".
However, for these failure cases, the distance computed for Manual Landing is consistent with the average landing distance achieved with Autoland.
Consequently, the flight crew can set the LDG TECHNIQUE field to Manual.

For more information about this limitation:
- *Refer to PER-LND-LCF-AFS ECAM Alerts*
- *Refer to PER-LND-LFF-IOI Conditions* .

SYNCHRONIZATION WITH ECAM - MEL DISPATCH

In the case of a dispatch with a MEL item resulting from an ECAM alert affecting landing performance during the previous flight, the list of the ECAM Alert items is still on the STATUS MORE page of the SD . The list of the ECAM Alert items of the previous flight is sent to LDG PERF.

Workaround:
- If there is no additional ECAM alert during the current flight: Manually deselect the list of the ECAM Alert items in LDG PERF
- If there are additional ECAM alerts during the current flight: Deselect the list of the ECAM Alert items in LDG PERF that are linked to the MEL dispatch.

For more information about this limitation:
- *Refer to PER-LND-LCF-AFS ECAM Alerts*
- *Refer to PER-LND-LCF-AFS Synchronization with ECAM* .

RLD AUTOLAND

LDG PERF does not automatically check that the RLD for automatic landing is higher than or equal to the RLD in manual mode.

Workaround:
- Run two calculations with LDG PERF: one with the Manual landing technique and one with the Autoland landing technique
- Retain for automatic landing the greatest of the following values:
  - RLD calculated using the Autoland landing technique
  - RLD calculated using the Manual landing technique

For more information about this limitation, *Refer to PER-LND-LRD-DSR Landing Distances* .

LANDING WEIGHT

When the flight crew switches between LDG PERF and LOADSHEET while a LDG PERF computation is running, the LDG PERF RESULTS panel may display results for a weight different from the one displayed in the CONDITIONS panel.
Workaround: Do not switch from LDG PERF to LOADSHEET while a LDG PERF calculation is running.

For more information about this limitation:
- *Refer to PER-LND-LCD-ACC Landing Weight*
- *Refer to PER-LND-LCF-ACC Landing Weight* .

CDL

Missing Items

When a CDL item is selected, the number of missing items is hidden in the ACFT STS box.
Workaround: Use the scroll bar to display the hidden information.

For more information about this limitation:
- *Refer to PER-LND-LCD-AFS CDL*
- *Refer to PER-LND-LCF-AFS CDL* .

ΔVref Speed Increment in VAPP when no ECAM Alert Selected

If no ECAM alert item is selected and if the flight crew selects a CDL item that has an impact on the VAPP , the associated increment in VAPP (ΔVref) is not displayed on the RESULTS panel. However, the landing computation is correct.
If no ECAM alert item is selected and if the flight crew selects a CDL item that has no impact on the VAPP , an additional result ΔVref appears on the RESULTS panel. This label should not be displayed. However, the landing computation is correct.
For more information about this limitation, *Refer to PER-LND-LCF-AFS CDL* .

IN-FLIGHT

CLB, CRZ, DES, HLD AND PLAN MODULES

MEL Items

MEL items are not implemented.
For more information about this limitation, *Refer to PER-IFT-ACS MEL* .

CDL Items

Ticked CDL items from the AFM are not transferred to IN-FLT PERF.
Workaround: Select directly the CDL items in IN-FLT PERF.
For more information about this limitation, *Refer to PER-IFT-ACS CDL* .

CDL Negligible Items

If the flight crew selects only CDL negligible items, the IN-FLT PERF computation fails.
For more information about this limitation, *Refer to PER-IFT-ACS CDL* .

DES MODULE - ALL ENGINES FLAMES OUT

The All Engines Flames Out Descent computation fails.
Refer to PER-IFT-DES-DSD Engines Operative .

CRZ AND PLAN MODULE

NSC Items - Mach Speed Input

When the flight crew uses a Mach number speed input, the IN-FLT PERF computation fails for the following NSC items:
- L/G EXTENDED
- DISPATCH WITH GEAR DOWN
- L/G DOORS OPEN.

Workaround: Use a CAS entry (the CAS vs. Mach conversion is computed by the ATMO module).

For more information about this limitation:
- *Refer to PER-IFT-ACS-NSC L/G*
- *Refer to PER-IFT-ACS-NSC L/G DOORS* .

Turbulence Speed - Cruise Altitude Below the Crossover Altitude

When the flight crew enters a cruise altitude below the Crossover Altitude, the IN-FLT PERF Turbulence Speed computation fails.
Workaround: Run a Selected Speeds computation when the altitude is below the Crossover Altitude.
For more information about this limitation, *Refer to PER-IFT-CRZ-TBS Turbulence Speed* .

PLAN MODULE - ECAM ALERTS - FUEL PENALTY FACTOR

The PLAN module does not display any fuel penalty linked to the selected ECAM Alerts item.

The flight crew should apply the following calculation sequence to assess the average fuel penalty along the remaining distance:

1. The computation is first made at current conditions without ECAM Alerts item
2. On the RESULTS panel, the flight crew notes down the Trip Fuel (F1)
3. The flight crew restarts the computation with the adequate ECAM Alerts item
4. On the RESULTS panel, the flight crew notes down the new Trip Fuel (F2)
5. The flight crew manually calculates the fuel penalty factor:
   Fuel Penalty Factor (%) = 100 x (F2 – F1) / F1.

For more information about this limitation, *Refer to PER-IFT-IFF Impact on Results* .

LOADSHEET

MANUAL FUEL DISTRIBUTION

In the case of a manual fuel distribution, the sum of all tanks (distribution section FOB) must be exactly identical to the total FOB (loading section FOB): there is no tolerance.
For more information about this limitation, *Refer to PER-LOD-LAI-FUL Fuel Distribution Section* .

MAXIMUM FOB

LOADSHEET computations fail when the flight crew enters the maximum FOB for the aircraft.
Workaround: Reduce the FOB by 150 kg .
For more information about this limitation, *Refer to PER-LOD-LAI-FUL Fuel Loading Section* .

MEL - FUEL DISTRIBUTION

If the flight crew selects a MEL item with an impact on Fuel Distribution, the associated non standard fuel distribution is not computed.
Workaround: Use the Manual Distribution function with the fuel quantities read on the ECAM .
For more information about this limitation, *Refer to PER-LOD-ACS MEL* .

OPERATING DATA - NSC AND CDL

Do not perform ATMO calculation with Non Standard Configurations (NSC) items or CDL items.

ATMO module calculations:
- Do not take into account NSC
- Fail when the flight crew selects a CDL item.

For more information about this limitation:

- *Refer to PER-OPD-AMISC ATMO Module Interface (Speed conversions)*
- *Refer to PER-OPD-AMITA ATMO Module Interface (True altitude for high altitude use)*
- *Refer to PER-OPD-AMILA ATMO Module Interface (Low altitude temperature corrections)* .

PRINTERS

Applicable to: ALL

The reference information is the information that appears on the different display units and OIT. In the case of a discrepancy between the printed and displayed information, the flight crew should use the displayed information for flight and fuel planning, ATC communication, etc.

APU LIMITATIONS GENERAL

Applicable to: ALL

APU START

In the case of an aborted APU start, the flight crew must wait 60 s before a new start attempt.

L2 This 60 s period is due to the ECB inhibition logic after an aborted APU start.

L1 After three consecutive APU start attempts, the flight crew must wait 60 min before a new start attempt.

L2 This 60 min period is to allow the APU starter to cool down.

ROTOR SPEED

Maximum N1 speed..... 106 %
Maximum N2 speed..... 102 %

EGT

Maximum indicated EGT ..... 900 °C
Maximum EGT for APU start..... 700 °C on ground, 800 °C in flight
Maximum EGT for APU running..... 900 °C during 30 s, or 935 °C during 0.5 s

Intentionally left blank

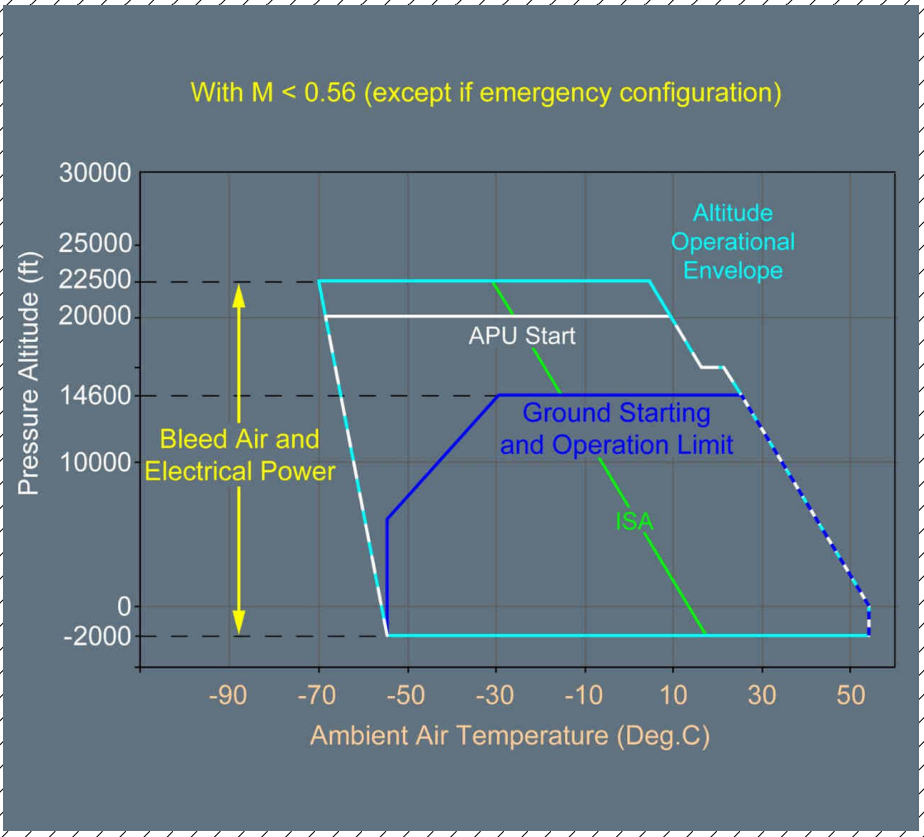
OPERATIONAL ENVELOPE

Applicable to: ALL
Impacted by TDU: 00018905 Operational Envelope

OPERATIONAL ENVELOPE

In the case of an all engine flame out, the APU can operate at any aircraft speed.
Otherwise, the APU can operate, when the aircraft speed is below M 0.56.

APU Operational Envelope



APU GENERATORS

L2 L1 On ground, each APU generator can supply up to 120 KVA.
On ground, both APU generators can operate.

In flight, up to 22 500 ft, only one APU generator can operate.

APU BLEED AIR SUPPLY

APU bleed air can be supplied up to 22 500 ft, provided the aircraft airspeed is below M 0.56.
Use of APU bleed air for wing anti-ice is not permitted.

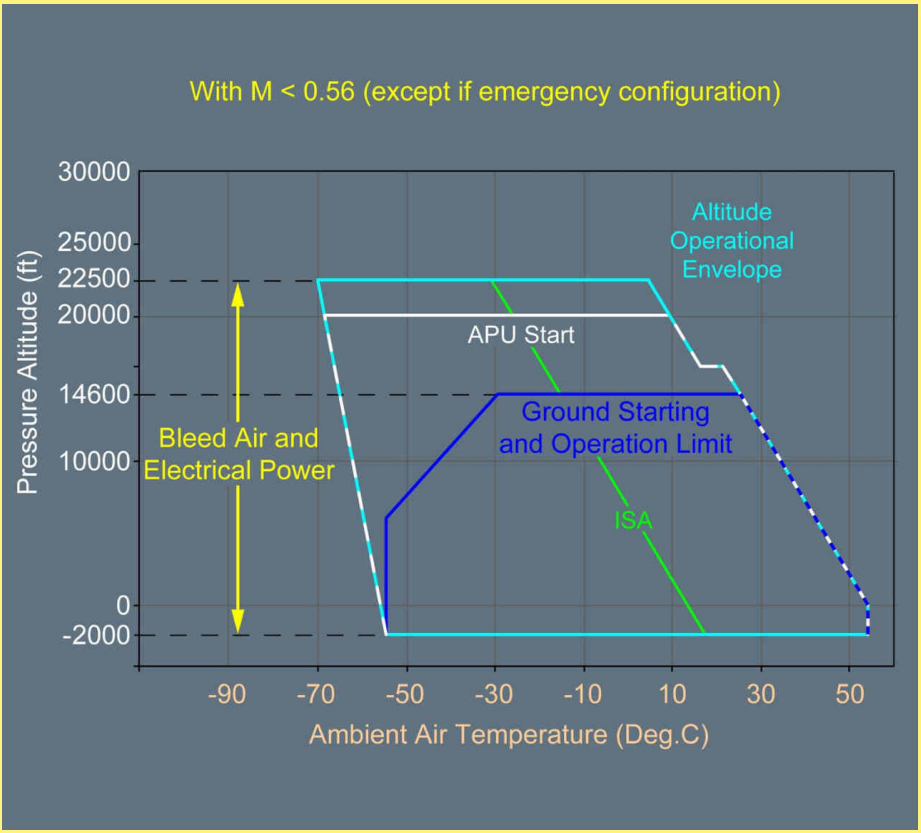
OPERATIONAL ENVELOPE

Applicable to: ALL
Impacted DU: 00004292 Operational Envelope

OPERATIONAL ENVELOPE

In the case of an all engine flame out, the APU can operate at any aircraft speed.
Otherwise, the APU can operate, when the aircraft speed is below M 0.56.
In addition, the APU start may not be successful below -30 °C (on ground and in flight).

APU Operational Envelope



APU GENERATORS

L2 On ground, each APU generator can supply up to 120 KVA.

L1 On ground, both APU generators can operate.

In flight, up to 22 500 ft, only one APU generator can operate.

APU BLEED AIR SUPPLY

APU bleed air can be supplied up to 22 500 ft, provided the aircraft airspeed is below M 0.56.

Use of APU bleed air for wing anti-ice is not permitted.

Reverse Thrust..... E
Reduced Thrust Takeoff..... F

Intentionally left blank

THRUST SETTING/EGT LIMITS

Applicable to: ALL

Operating Condition		Time Limit	EGT Limit
Takeoff and Go-around	All engines operative	5 min	1 002 °C
	One engine inoperative	10 min	
Maximum Continuous Thrust (MCT)		Not limited	970 °C
Starting	On ground		745 °C
	In flight		865 °C

OIL

Applicable to: ALL

Maximum continuous temperature..... 177 °C during 5 s or 163 °C during 20 min
Minimum starting temperature..... –40 °C
Minimum temperature prior to takeoff..... 50 °C
Minimum oil quantity..... *Refer to PRO-NOR-SOP-50-E Before Walkaround_ECAM PAGES*
Minimum oil Pressure..... 25 PSI

SHAFT SPEEDS

Applicable to: ALL

N1 max..... 111 %
N2 max..... 118.7 %

STARTER

Applicable to: ALL

Three periods of 5 min continuous starter use are possible.

L2 The FADEC monitors the starter-on time. When the starter-on time exceeds 5 min continuous operation, the ENG x START FAULT STARTER TIME EXCEEDED ECAM alert triggers. The starter-on time resets when the flight crew sets to off the ENG MASTER lever.

L3 The starter-on time begins when the flight crew sets to on the ENG MASTER lever and stops when the starter disengages, i.e. when N2 is 58.4 %.

L1 After a long period of use, a starter cool down period is required, approximately 2 min cool down for each minute of starter time.

When the starter accumulates 15 min of use, the starter must cool down for 30 min before a new engine start is attempted.

If the N2 is above 25 %, no running engagement of the starter is possible.

Note: *High tailwinds (i.e. higher than 25 kt) may have an adverse effect on start. It may be necessary to reposition the airplane into the wind.*

REVERSE THRUST

Applicable to: ALL

- Selection of the reverse thrust is prohibited in flight
- Backing the aircraft with reverse thrust is not permitted
- Maximum reverse should not be used below 70 kt (or when the indication starts to fluctuate). Idle reverse is allowed down to aircraft stop.

REDUCED THRUST TAKEOFF

Applicable to: ALL

Takeoff at reduced thrust is allowed only if the airplane meets all performance requirements at the takeoff weight, with the operating engines at the thrust available for the flex temperature.
Takeoff at reduced thrust is allowed with any inoperative item affecting the performance only if the associated performance shortfall has been applied to meet the above requirements.

Note: *Allowed inoperative items may be identified through DISPATCH WITH INOPERATIVE ITEM chapter of the AFM or the MMEL*

Takeoff at reduced thrust is not allowed on contaminated runways.

The flex temperature must not be:
- Higher than ISA + 60 °C
- Lower than the flat rating temperature or actual OAT.

Takeoff at reduced thrust is not allowed unless the operator establishes a means to verify the availability of takeoff thrust to ensure that the engine deterioration does not exceed authorized limits.

IN-FLT PERF APPLICATION - ATMO MODULE

Applicable to: ALL

The IN-FLT PERF application is made of 6 modules (CLB, CRZ, DES, HLD, PLAN and ATMO).

The ATMO module provides the flight crew with a means to convert speeds and to consult ISA tables for:

- Given meteorological conditions
- A given standard aircraft configuration.

The main results of this module are:

- Speed conversions
- True altitude for high altitude use
- Low altitude temperature corrections
- ISA information.

Intentionally left blank

ATMO MODULE INTERFACE (SPEED CONVERSIONS)

Applicable to: ALL

IN-FLT PERF ATMO Module Interface

CONDITIONS

The flight crew can define the current outside conditions.
For more information about the CONDITIONS panel, *Refer to PER-OPD-CDTSC CONDITIONS Panel* .

SPECIFIC DATA

The flight crew can define the specific data needed for the computation of the operating data.
For more information about the SPECIFIC DATA panel, *Refer to PER-OPD-SDSC SPECIFIC DATA Panel* .

AIRCRAFT STATUS

Do not perform ATMO calculation with NSC items or CDL items.

ATMO module calculations:
- Do not take into account Non Standard Configurations (NSC)
- Fail when the flight crew selects a CDL item.

RESULTS

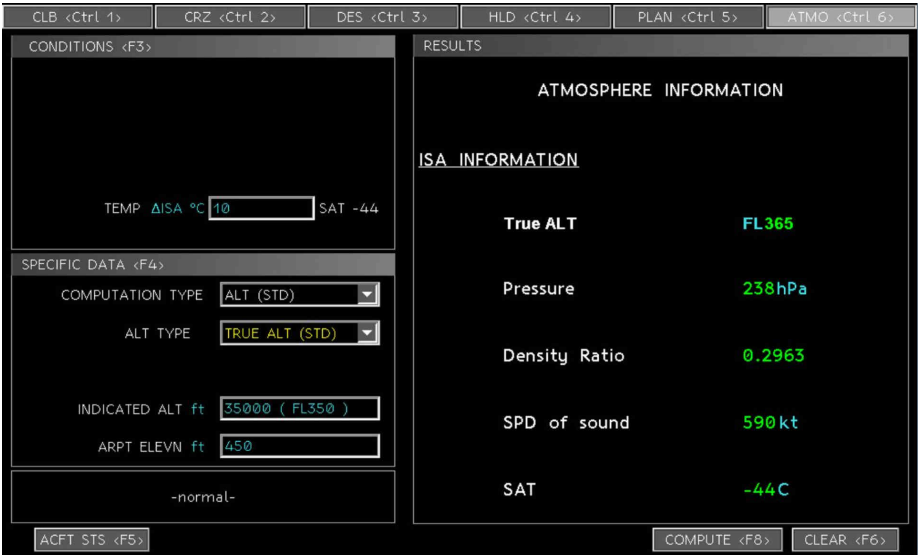
The RESULTS panel displays:

- Conversions
  For more information about the Conversions, *Refer to Atmosphere Results - Conversions*
- ISA Information.
  For more information about the ISA Information, *Refer to Atmosphere Results - ISA Information*

ATMO MODULE INTERFACE (TRUE ALTITUDE FOR HIGH ALTITUDE USE)

Applicable to: ALL

IN-FLT PERF ATMO Module Interface



CONDITIONS

The flight crew can define the current outside conditions.
For more information about the CONDITIONS panel, *Refer to PER-OPD-CDTTA CONDITIONS Panel* .

SPECIFIC DATA

The flight crew can define the specific data needed for the computation of the operating data.
For more information about the SPECIFIC DATA panel, *Refer to PER-OPD-SDTA SPECIFIC DATA Panel* .

AIRCRAFT STATUS

Do not perform ATMO calculation with NSC items or CDL items.

ATMO module calculations:
- Do not take into account Non Standard Configurations (NSC)
- Fail when the flight crew selects a CDL item.

RESULTS

The RESULTS panel displays ISA Information.
For more information about the ISA Information, refer to *Refer to Atmosphere Results - ISA Information* .

ATMO MODULE INTERFACE (LOW ALTITUDE TEMPERATURE CORRECTIONS)

Applicable to: ALL

IN-FLT PERF ATMO Module Interface

CONDITIONS

No outside conditions are necessary to compute the low altitude temperature corrections.

SPECIFIC DATA

The flight crew can define the specific data needed for the computation of the operating data. For more information about the SPECIFIC DATA panel, *Refer to PER-OPD-SDLA SPECIFIC DATA Panel* .

AIRCRAFT STATUS

Do not perform ATMO calculation with NSC items or CDL items.

ATMO module calculations:
- Do not take into account Non Standard Configurations (NSC)
- Fail when the flight crew selects a CDL item.

RESULTS

The RESULTS panel displays the low altitude temperature corrections.

For more information about the low altitude temperature corrections, refer to *Refer to Atmosphere Results - Low Altitude Temperature Corrections* .

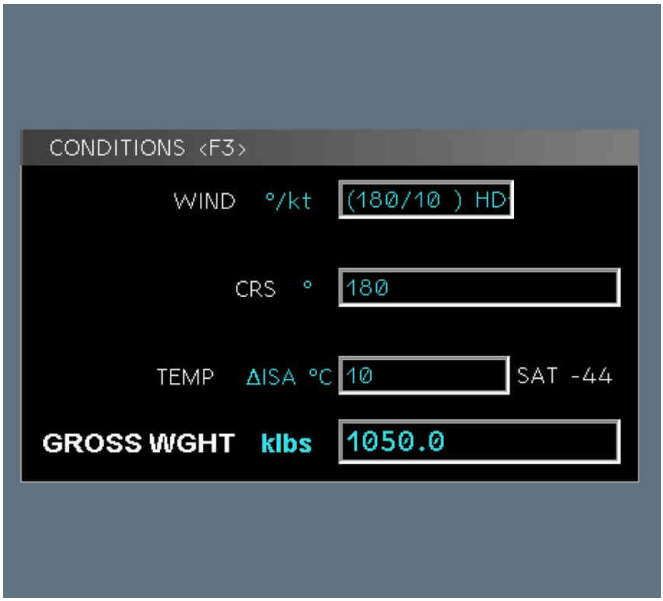
CONDITIONS PANEL

Applicable to: ALL

The CONDITIONS panel provides the following information:

- Wind
- Course
- Temperature (Δ ISA)
- Gross weight.

CONDITIONS Panel



WIND

Applicable to: ALL

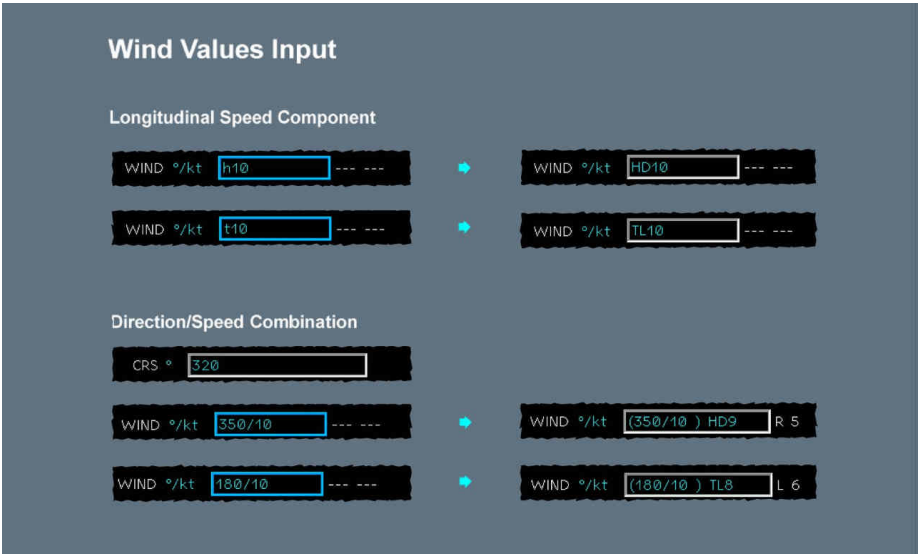
GENERAL

The wind affects the Ground Speed (GS). A tailwind will induce an increase in GS.

ATMO

There are two ways of defining wind values:
- Longitudinal Speed Component
- Direction/Speed Combination.

Wind Values Input



LONGITUDINAL SPEED COMPONENT

It is possible to directly enter a longitudinal wind component.
The flight crew can use the codes “H” for a headwind and “T” for a tailwind.
The flight crew can also use the codes “HD” for a headwind and “TL” for a tailwind.

DIRECTION/SPEED COMBINATION

The flight crew can enter the combination of a direction and a speed.
The entry is projected along the course and perpendicular to the course.
The longitudinal projection follows the same display rules as the speed entry.

Crosswind is displayed as:
- R, if it comes from the right, or
- L, if it comes from the left.

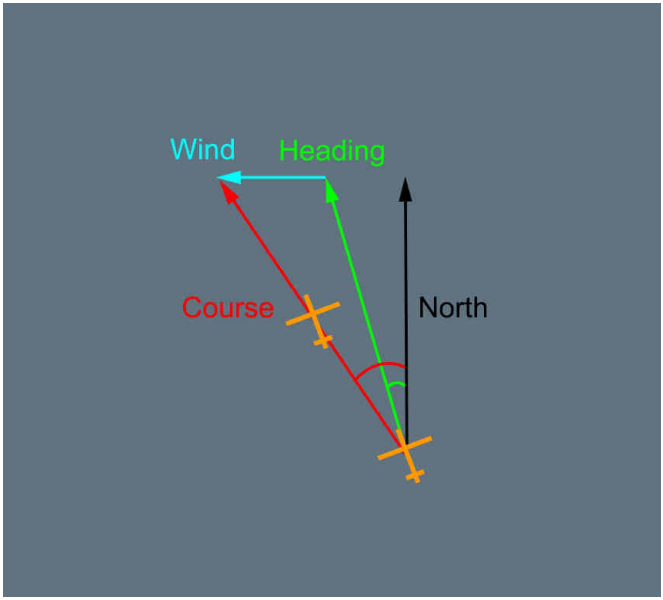
COURSE

Applicable to: ALL

GENERAL

The course defines the axis on which the wind is projected.

Course Definition



ATMO

The CRS field is only displayed if a wind has been entered in a combination of a direction and a speed.

L2 For more information about the wind, *Refer to PER-OPD-CDTSC Wind* .

TEMPERATURE

Applicable to: ALL

GENERAL

An increase in temperature (SAT or ΔISA) leads to:

- A higher True Air Speed (TAS) for the same Calibrated Air Speed (CAS) or Mach

L2 At fixed CAS, TAS is inversely proportional to air density, which decreases with temperature.
At fixed Mach, TAS increases with temperature.

L1 - A higher Ground Speed (GS)

- A higher true altitude at fixed indicated altitude
- A lower density ratio

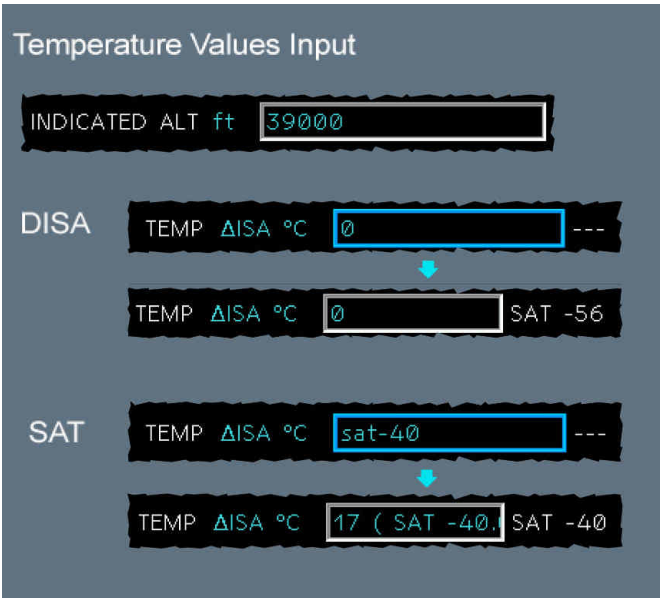
L2 The air density decreases with temperature.

L1 - A higher speed of sound

- A higher Total Air Temperature (TAT).

ATMO

Temperature Values Input



The TEMP field corresponds to a deviation from ISA law (ΔISA).

The flight crew can enter a temperature as:
- A ΔISA, or
- A Static Air Temperature (SAT) at current pressure altitude, which is automatically converted into a ΔISA.

GROSS WEIGHT

Applicable to: ALL

GENERAL

At a fixed pressure altitude, any decrease in weight, due to fuel burn off for example, leads to lower ECON and LRC Mach.

ATMO

The flight crew enters the current aircraft weight.
This gross weight (GROSS WGHT field) must be between the Operating Empty Weight (OEW) and the Maximum Design Takeoff Weight (MTOW).

Intentionally left blank

CONDITIONS PANEL

Applicable to: ALL

CONDITIONS Panel

GENERAL

An increase in temperature (SAT or ΔISA) leads to:

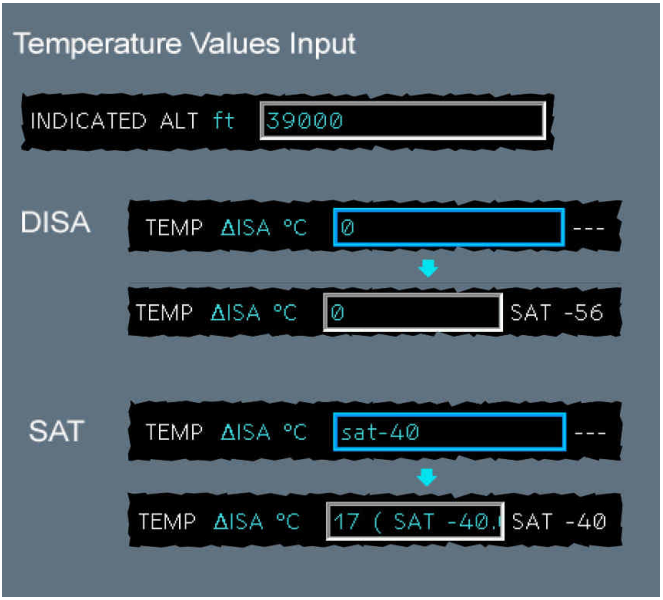
- A higher true altitude at fixed indicated altitude
- A lower density ratio

L2 The air density decreases with temperature.

L1 - A higher speed of sound.

ATMO

Temperature Values Input



The TEMP field corresponds to a deviation from ISA law (ΔISA).

The flight crew can enter a temperature as:
- A ΔISA, or
- A Static Air Temperature (SAT) at current pressure altitude, which is automatically converted into a ΔISA.

SPECIFIC DATA PANEL

Applicable to: ALL

The SPECIFIC DATA panel includes the following information:

- Computation type
- Speed type
- Indicated altitude
- Airport elevation.

SPECIFIC DATA Panel

COMPUTATION TYPE

Applicable to: ALL

The flight crew uses the COMPUTATION TYPE drop-down list to select one of the following computation types:

- SPEED, to compute speed conversions and ISA Information
- ALT (STD), to compute true altitude for high altitude use or low altitude temperature corrections.

SPEED TYPE

Applicable to: ALL

The flight crew uses the SPD TYPE drop-down list to select one of the following speed types:
- Mach
- IAS
- ECON speed based on CI value
- LRC speed.

INDICATED ALTITUDE

Applicable to: ALL

GENERAL

A higher pressure altitude results in:
- A lower pressure
- A lower density ratio

L2 The air density decreases with altitude.

L1 - A lower speed of sound

L2 The speed of sound decreases when temperature decreases.

L1 - A lower SAT below the tropopause and a constant SAT above the tropopause
- A lower TAT at constant Mach.

TRUE AIR SPEED

At fixed CAS, TAS increases with altitude.

At fixed Mach, TAS is proportional to SAT, which:
- Decreases with altitude below the tropopause
- Remains constant above the tropopause.

ECON AND LRC MACH

ECON and LRC Mach increase with pressure altitude.

ATMO

The flight crew enters the pressure altitude.

AIRPORT ELEVATION

Applicable to: ALL

GENERAL

The elevation of the intended airport impacts the true altitude if there is deviation from ISA law.
For a positive ΔISA, a higher elevation of the intended airport results in a lower true altitude.
For a negative ΔISA, a higher elevation of the intended airport results in a higher true altitude.

ATMO

The flight crew enters the elevation of the intended airport.
For high altitude use, the flight crew may enter 0.

Intentionally left blank

SPECIFIC DATA PANEL

Applicable to: ALL

The SPECIFIC DATA panel includes the following information:

- Computation type
- Altitude type
- Indicated altitude
- Airport elevation.

SPECIFIC DATA Panel

COMPUTATION TYPE

Applicable to: ALL

The flight crew uses the COMPUTATION TYPE drop-down list to select one of the following computation types:

- SPEED, to compute speed conversions and ISA Information
- ALT (STD), to compute true altitude for high altitude use or low altitude temperature corrections.

ALTITUDE TYPE

Applicable to: ALL

The flight crew uses the ALT TYPE drop-down list to select one of the following altitude types:
- TRUE ALT (STD), to compute true altitude for high altitude use
- LO ALT TEMP CORR, to compute low altitude temperature corrections.

INDICATED ALTITUDE

Applicable to: ALL

GENERAL

A higher pressure altitude results in:
- A lower pressure
- A lower density ratio

L2 The air density decreases with altitude.

L1 - A lower speed of sound

L2 The speed of sound decreases when temperature decreases.

L1 - A lower SAT below the tropopause and a constant SAT above the tropopause.

ATMO

The flight crew enters the pressure altitude.

AIRPORT ELEVATION

Applicable to: ALL

GENERAL

The elevation of the intended airport impacts the true altitude if there is deviation from ISA law.
For a positive ΔISA, a higher elevation of the intended airport results in a lower true altitude.
For a negative ΔISA, a higher elevation of the intended airport results in a higher true altitude.

ATMO

The flight crew enters the elevation of the intended airport.
For high altitude use, the flight crew may enter 0.

SPECIFIC DATA PANEL

Applicable to: ALL

The SPECIFIC DATA panel includes the following information:

- Computation type
- Altitude type
- Height above airport elevation
- Airport elevation
- Airport temperature.

SPECIFIC DATA Panel

COMPUTATION TYPE

Applicable to: ALL

The flight crew uses the COMPUTATION TYPE drop-down list to select one of the following computation types:

- SPEED, to compute speed conversions and ISA Information
- ALT (STD), to compute true altitude for high altitude use or low altitude temperature corrections.

ALTITUDE TYPE

Applicable to: ALL

The flight crew uses the ALT TYPE drop-down list to select one of the following altitude types:
- TRUE ALT (STD), to compute true altitude for high altitude use
- LO ALT TEMP CORR, to compute low altitude temperature corrections.

HEIGHT ABOVE AIRPORT LEVEL

Applicable to: ALL

GENERAL

The Height Above the Airport Level (HGT AAL) is a minimum promulgated height above the elevation of the altimeter setting.
At the same airport temperature, the higher the HGT AAL, the higher the altitude correction to add to the minimum promulgated height.

ATMO

The flight crew enters the HGT AAL.

AIRPORT ELEVATION

Applicable to: ALL

GENERAL

A higher airport elevation results in a slightly lower altitude correction.

ATMO

The flight crew enters the elevation of the intended airport.

AIRPORT TEMPERATURE

Applicable to: ALL

GENERAL

A decrease in temperature leads to a higher altitude correction.

ATMO

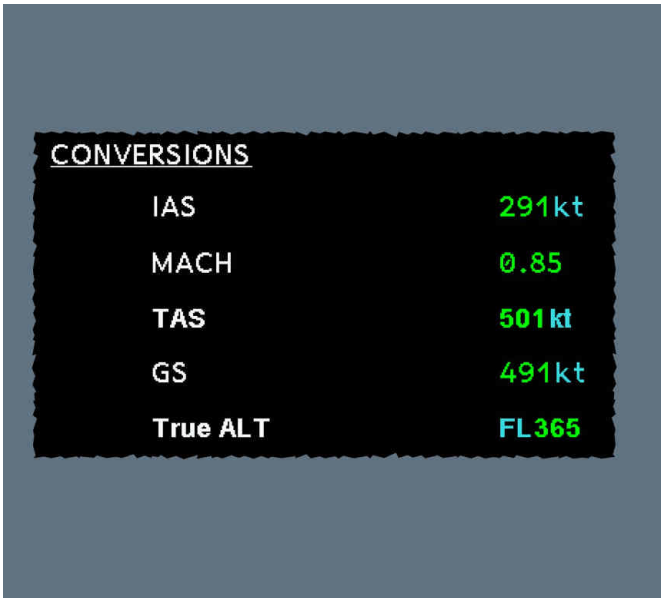
The flight crew enters the Outside Air Temperature (OAT) at the intended airport.

CONVERSIONS

Applicable to: ALL

The CONVERSIONS subpanel provides the essential information for the conversion of typical operating speeds and altitudes.

CONVERSIONS Subpanel



IAS

This value is the instantaneous Indicated Air Speed (IAS) for current conditions.

MACH

This value is the instantaneous Mach number for current conditions.

TAS

This value is the instantaneous True Air Speed (TAS) for current conditions.

GS

This value is the instantaneous Ground Speed (GS) for current conditions.

TRUE ALT

This value is the true altitude of the airplane for current conditions.

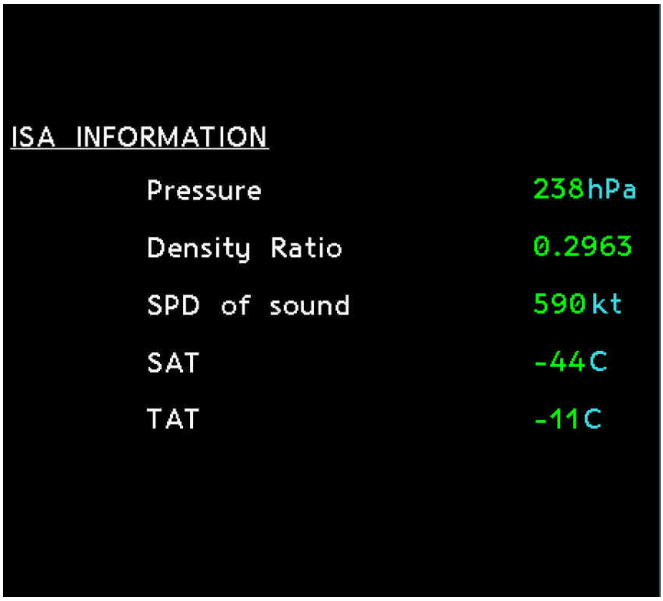
ISA INFORMATION

Applicable to: ALL

SPEED COMPUTATION TYPE

The ISA INFORMATION subpanel provides the essential information on atmospheric data.

ISA INFORMATION Subpanel



PRESSURE

This value is the standard pressure for current conditions.

DENSITY RATIO

This value is the standard density ratio for current conditions.

SPD OF SOUND

This value is the speed of sound for current conditions.

SAT

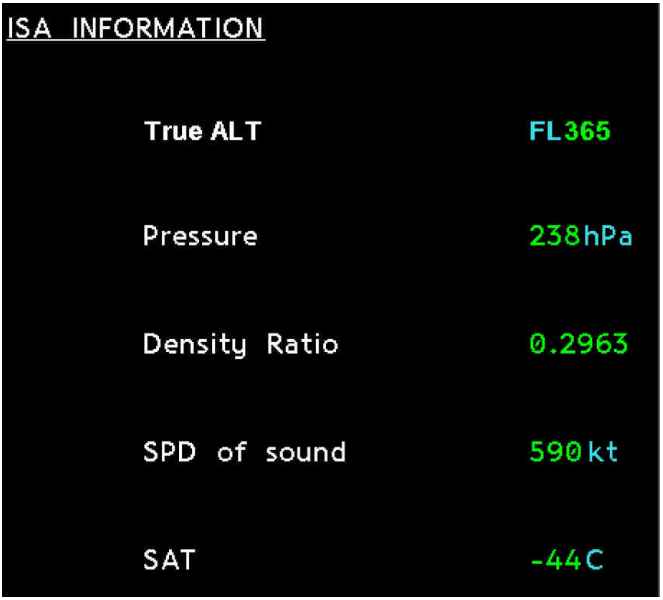
This value is the Static Air Temperature (SAT) for current conditions.

TAT

This value is the Total Air Temperature (TAT) for current conditions.

TRUE ALT

ISA INFORMATION Subpanel



TRUE ALT

This value is the true altitude of the airplane for current conditions.

PRESSURE

This value is the standard pressure for current conditions.

DENSITY RATIO

This value is the standard density ratio for current conditions.

SPD OF SOUND

This value is the speed of sound for current conditions.

SAT

This value is the Static Air Temperature (SAT) for current conditions.

LOW ALTITUDE TEMPERATURE CORRECTIONS

Applicable to: ALL

The RESULTS panel provides:

- Correction: The altitude correction to add to the minimum promulgated height. This altitude correction for low altitude use is the consequence of the low airport temperature
- Corrected Height Above Airport Level (AAL): The minimum promulgated height + Correction.

RESULTS Panel

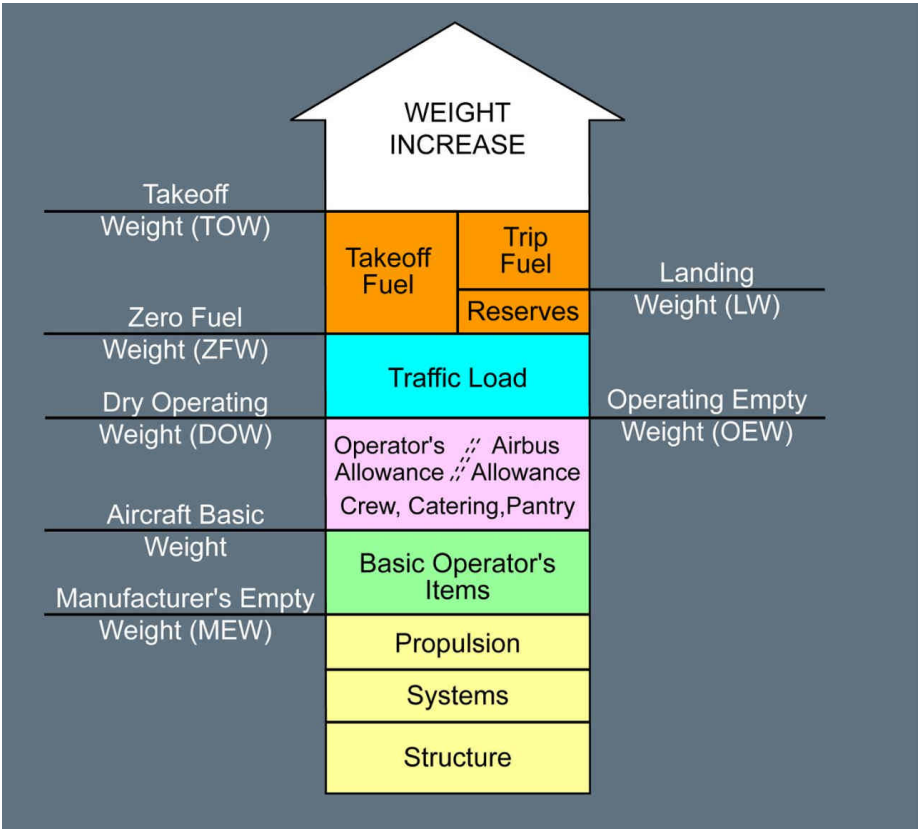
WEIGHTS

Applicable to: ALL

Weights



MANUFACTURER'S EMPTY WEIGHT (MEW)

Manufacturer's Empty Weight (MEW) refers to the weight of the aircraft structure, power plant, furnishings, systems and other items of equipment that are considered as part of the manufacturer's aircraft. MEW includes fluids contained in closed systems (e.g. hydraulic fluid).

AIRCRAFT BASIC WEIGHT

Aircraft basic weight refers to the MEW plus basic Operator items, that are on board the aircraft for every flight. Basic Operator items include unusable fuel, engine oil, emergency equipment, toilet chemicals and fluids, galley structure, seats and documentation, etc.

OPERATING EMPTY WEIGHT (OEW)

Operating Empty Weight (OEW) refers to the basic weight of the aircraft, plus any items specific to the flight (e.g. catering, water, cabin crew, miscellaneous), also referred to as variable Operator items. Airbus defines a standard weight for these variable Operator items. The OEW is published in the aircraft Wheighing Report. The OEW is not used as an operational weight.

DRY OPERATING WEIGHT (DOW)

The Dry Operating Weight (DOW) refers to the basic weight of the aircraft, plus any items specific to the flight (e.g. catering, water, cabin crew, miscellaneous), also referred to as variable Operator items. The Operator defines the actual weight of these variable Operator items for each flight. This weight is the starting weight of the load and trim sheet for a specific flight.

T.O FUEL

Takeoff fuel weight is the weight of the fuel on board the aircraft at takeoff. T.O fuel weight refers to the weight of the Fuel On Board (FOB) at the gate, minus taxi fuel

OPERATING WEIGHT

Operating weight is the weight obtained by adding the DOW and the T.O fuel weight. Ground personnel use the operating weight in the load message, in order to determine the underload.

TOTAL TRAFFIC LOAD

Total traffic load is the weight of the payload including cargo loads, passengers and baggage of passengers.

TRIP FUEL

Trip fuel weight is the weight of the fuel necessary to fly from departure to destination, without fuel reserves. Trip fuel is equal to T.O fuel minus the fuel reserves.

ZERO FUEL WEIGHT (ZFW)

Zero Fuel Weight (ZFW) is the weight obtained by adding the DOW and the total traffic load weight. The flight crew must check that the ZFW is below MZFW and above the minimum weight (the lowest weight displayed in the CG diagram). The MZFW depends on the CG.

The MZFW may be reduced, depending on:
- Loading

- MEL items.

TAKEOFF WEIGHT (TOW)

Takeoff Weight (TOW) is the total weight of the aircraft at takeoff, it is obtained by adding the ZFW and the T.O fuel weight. The flight crew must check that the TOW is below MTOW.

The MTOW may be reduced, depending on:
- Takeoff performance
- MEL items.

LANDING WEIGHT (LW)

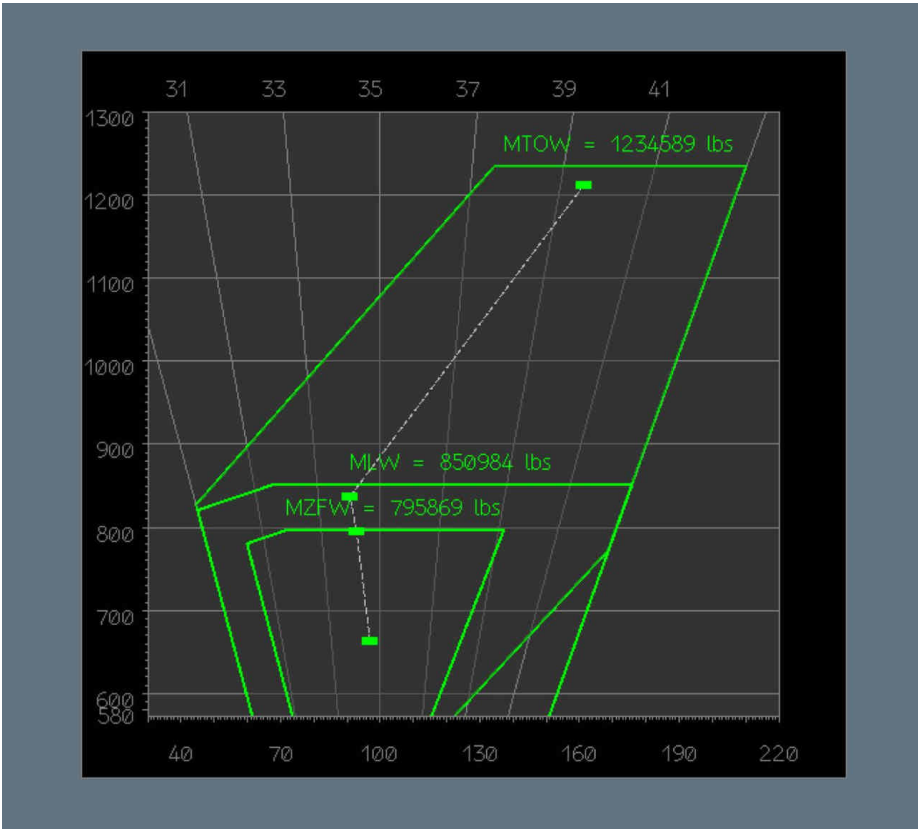
Landing Weight (LW) is the total weight of the aircraft at landing. It is equal to the TOW minus trip fuel. The flight crew must check that the LW is below MLW. The MLW depends on the CG.

The MLW may be reduced, depending on:
- Loading
- Landing performance
- MEL items.

CGS

Applicable to: ALL

CG Diagram



For each flight, the flight crew must check that the ZFW/CG, TOW/CG, and LW/CG do not exceed the corresponding operational CG envelopes.

LOADSHEET APPLICATION

Applicable to: ALL

The loadsheet application computes aircraft weights and corresponding CG positions before dispatch.

Two modes of data entry are available:
- Detailed: Requires all aircraft loading entries (variable Operator items, payload, fuel), and is used as an electronic load and trim sheet
- Reduced: Uses ZFW/CG (computed by the ground) and fuel data to compute TOW/CG and LW/CG.

LOADSHEET APPLICATION PARAMETERS (REDUCED MODE)

Applicable to: ALL

In reduced mode, the flight crew must enter the following parameters:
- Aircraft configuration, by selecting the appropriate configuration code
- MTOW/MLW, in the case of a weight restriction due to MEL items
- ZFW/CG, in order to define aircraft loading
- Fuel On Board (FOB)
- Trip Fuel
- Taxi Fuel, if necessary
- Fuel Density, if necessary.

In reduced mode, the flight crew can enter the following parameters:
- LMC, in order to define the final ZFW/CG with additional passengers and cargo, either:
  - As a total weight (total), or
  - In detail (distributed).
- Trim tank quantity (in trim adjustment mode)
- Fuel weight per tank (in manual distribution mode).

LOADSHEET APPLICATION PARAMETERS (DETAILED MODE)

Applicable to: ALL

In detailed mode, the flight crew must enter the following parameters:

- Aircraft configuration, by selecting the configuration code and defining the variable Operator items. These items define the DOW/CG by adding crew, catering and the additional items to the predefined aircraft basic weight
- MTOW/MLW, in the case of a weight restriction due to MEL items
- Payload (passengers and cargo) and its distribution, in order to define the ZFW/CG by adding payload and DOW
- Fuel On Board (FOB)
- Trip Fuel
- Taxi Fuel, if necessary
- Fuel Density, if necessary.

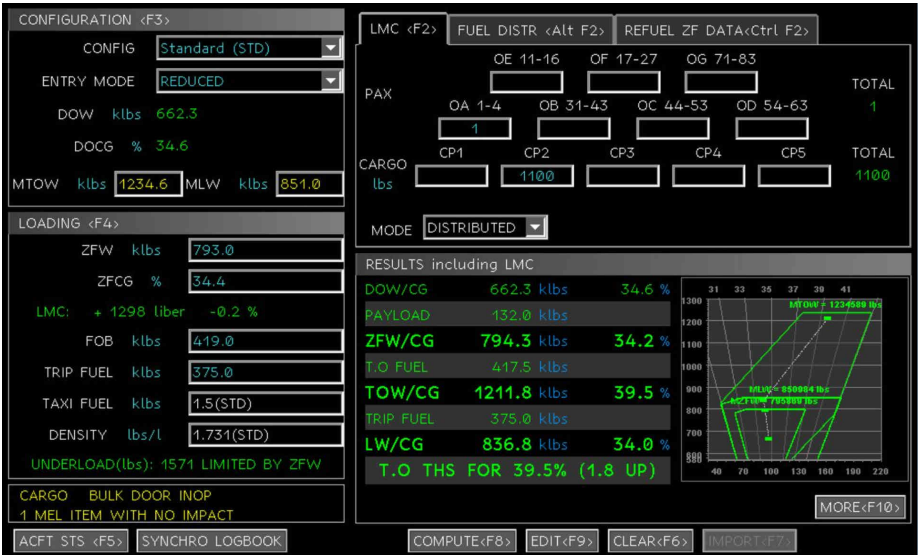
In detailed mode, the flight crew can enter the following parameters:

- Trim tank quantity (in trim adjustment mode)
- Fuel weight per tank (in manual distribution mode).

LOADSHEET APPLICATION INTERFACE (REDUCED MODE)

Applicable to: ALL

Loadsheet Application Interface



CONFIGURATION

The CONFIGURATION panel displays the configuration code, the entry mode, the DOW / DOCG , and the MTOW / MLW for the flight.

For more information about the CONFIGURATION panel,

- *Refer to PER-LOD-LAI-ACRO Aircraft Configuration Panel (Reduced Mode Only) - "Direct DOW/CG in Reduced Mode" Disabled* , or
- *Refer to PER-LOD-LAI-ACRO Aircraft Configuration Panel (Reduced Mode Only) - "Direct DOW/CG in Reduced Mode" Enabled* , or
- *Refer to PER-LOD-LAI-ACRD Aircraft Configuration Panel (Reduced Mode plus Detailed Mode) - "Direct DOW/CG in Detailed Mode" Disabled* , or
- *Refer to PER-LOD-LAI-ACRD Aircraft Configuration Panel (Reduced Mode plus Detailed Mode) - "Direct DOW/CG in Detailed Mode" Enabled* .

LOADING

The LOADING panel displays the loading of the aircraft entered by the flight crew:

ZFW / CG

The flight crew must enter the ZFW and ZFCG .

FUEL

The flight crew must enter the following fuel quantities:
- Fuel On Board (FOB)
- Trip fuel
- Taxi fuel, if necessary
- Fuel density, if necessary.

For more information about the fuel, *Refer to Fuel - Loading Section* .

DISTRIBUTION

These panels display the payload and fuel distribution information:

LMC

The flight crew can enter the Last Minute Changes (LMC).
For more information about the LMC , *Refer to PER-LOD-LAI-PRM Last Minute Changes (LMC)* .

FUEL DISTRIBUTION

After computation, this subpanel displays the predicted fuel distribution.
The flight crew can enter the detailed fuel distribution between tanks.
For more information about the fuel distribution, *Refer to Fuel - Distribution Section* .

REFUEL ZF DATA

The flight crew selects the ZFW / CG values to be used to compute the predicted fuel distribution according to the CG targeting logic.
For more information about the refuel ZF data, *Refer to PER-LOD-LAI-FUL REFUEL ZF DATA Panel* .

AIRCRAFT STATUS

The flight crew can select MEL items impacting loading capabilities.
For more information about the aircraft status, *Refer to PER-LOD-ACS AIRCRAFT STATUS Panel* .

SYNCHRO LOGBOOK

The flight crew can recover the eLogbook status by clicking on the "SYNCHRO LOGBOOK" button.
For more information about the SYNCHRO LOGBOOK function, *Refer to PER-LOD-ACS Synchronization with Logbook* .

RESULTS

The RESULTS panel displays the results of the weight and balance computation.
For more information about the results of the computation, *Refer to PER-LOD-LAO RESULTS Panel* .

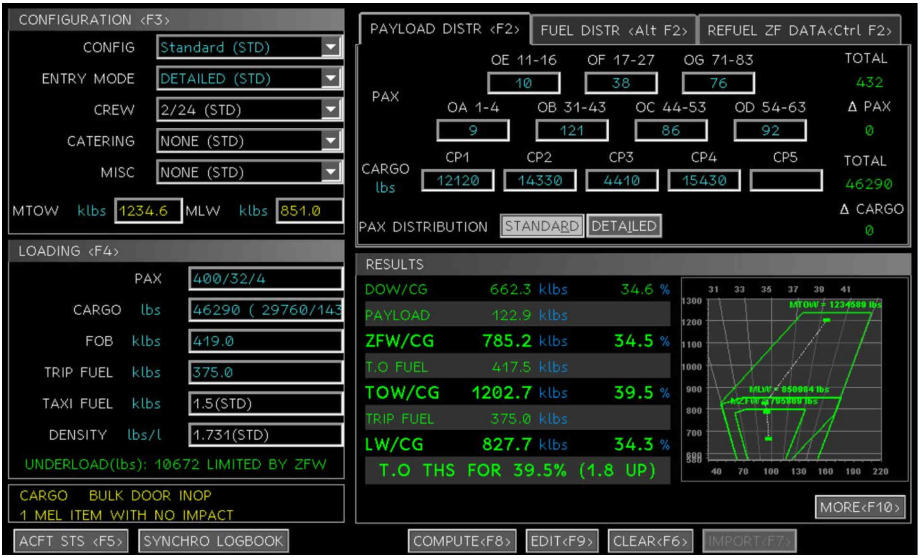
Applicable to: ALL

Loadsheet Application Interface



CONFIGURATION

The CONFIGURATION panel displays the aircraft configuration.
The flight crew can enter, if necessary, the crew composition, the catering and the additional loaded items part of the DOW / CG definition. The flight crew can also enter directly the DOW / DOCG .

For more information about the CONFIGURATION panel,

- *Refer to PER-LOD-LAI-ACDO Aircraft Configuration Panel (Detailed Mode Only)* , or
- *Refer to PER-LOD-LAI-ACRD Aircraft Configuration Panel (Reduced Mode plus Detailed Mode) - "Direct DOW/CG in Detailed Mode" Disabled* , or
- *Refer to PER-LOD-LAI-ACRD Aircraft Configuration Panel (Reduced Mode plus Detailed Mode) - "Direct DOW/CG in Detailed Mode" Enabled* .

LOADING

The LOADING panel displays the loading of the aircraft entered by the flight crew:

PAYLOAD

The flight crew must enter the pax and cargo.
For more information about the payload, *Refer to Payload - Loading Section* .

FUEL

The flight crew must enter the following fuel quantities:
- Fuel On Board (FOB)
- Trip fuel
- Taxi fuel, if necessary
- Fuel density, if necessary.

For more information about the fuel, *Refer to Fuel - Loading Section* .

DISTRIBUTION

These panels display the payload and fuel distribution information:

PAYLOAD DISTRIBUTION

The flight crew enters the payload distribution.
For more information about the payload distribution, *Refer to Payload - Distribution Section* .

FUEL DISTRIBUTION

This subpanel displays the fuel distribution.
The flight crew can enter the detailed fuel distribution between tanks.
For more information about the fuel distribution, *Refer to Fuel - Distribution Section* .

REFUEL ZF DATA

The flight crew can select the ZFW / CG values used to compute the fuel distribution according to the CG targeting logic.
For more information about the refuel ZF data, *Refer to PER-LOD-LAI-FUL REFUEL ZF DATA Panel* .

AIRCRAFT STATUS

The flight crew can select MEL items impacting loading capabilities.
For more information about the aircraft status, *Refer to PER-LOD-ACS AIRCRAFT STATUS Panel* .

SYNCHRO LOGBOOK

The flight crew can recover the eLogbook status by clicking on the "SYNCHRO LOGBOOK" button.
For more information about the SYNCHRO LOGBOOK function, *Refer to PER-LOD-ACS Synchronization with Logbook* .

RESULTS

The RESULTS panel displays the results of the weight and balance computation.
For more information about the results of the computation, *Refer to PER-LOD-LAO RESULTS Panel* .

Intentionally left blank

AIRCRAFT CONFIGURATION PANEL (REDUCED MODE ONLY) - "DIRECT DOW/CG IN REDUCED MODE" DISABLED

Applicable to: ALL

The CONFIGURATION panel includes the following information:

- Configuration
- DOW
- DOCG
- MTOW
- MLW.

Aircraft Configuration Panel

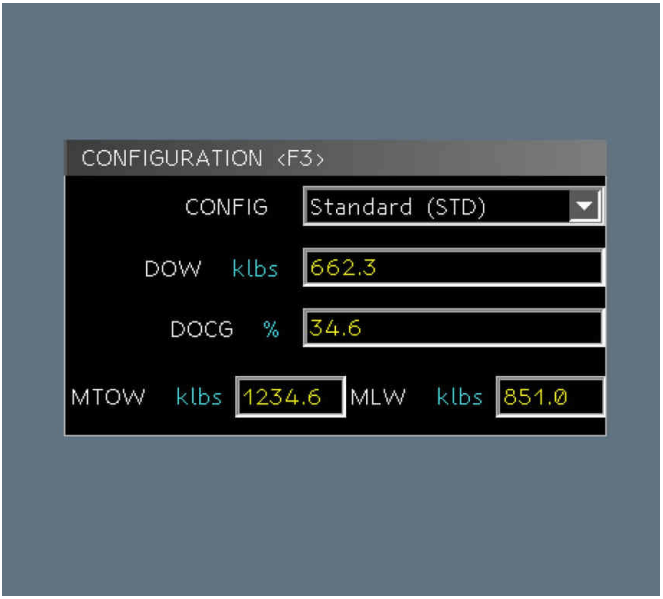
AIRCRAFT CONFIGURATION PANEL (REDUCED MODE ONLY) - "DIRECT DOW/CG IN REDUCED MODE" ENABLED

Applicable to: ALL

The CONFIGURATION panel includes the following information:

- Configuration
- DOW
- DOCG
- MTOW
- MLW.

Aircraft Configuration Panel



CONFIGURATION

Applicable to: ALL

The CONFIG drop down list enables the flight crew to select the applicable configuration. The following parameters will automatically be updated accordingly:

- Basic Weight
- Passenger average weight
- Aircraft CG limits
- User interface.

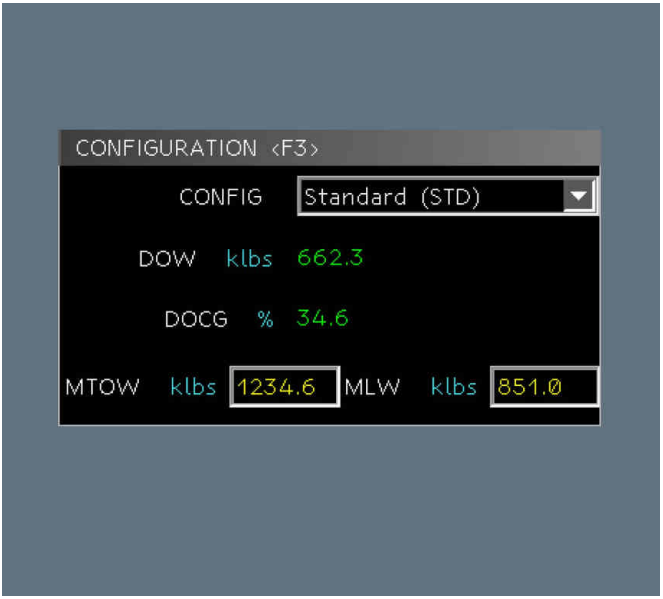
If more than one configuration is defined, the flight crew must select the configuration that is applicable to the current flight.

DOW/DOCG - "DIRECT DOW/CG IN REDUCED MODE" DISABLED

Applicable to: ALL

The DOW and DOCG fields display the default Dry Operating Weight (DOW) and the Dry Operating Center of Gravity (DOCG). The flight crew cannot modify the default DOW and DOCG. The values appear in green.

CONFIGURATION Panel



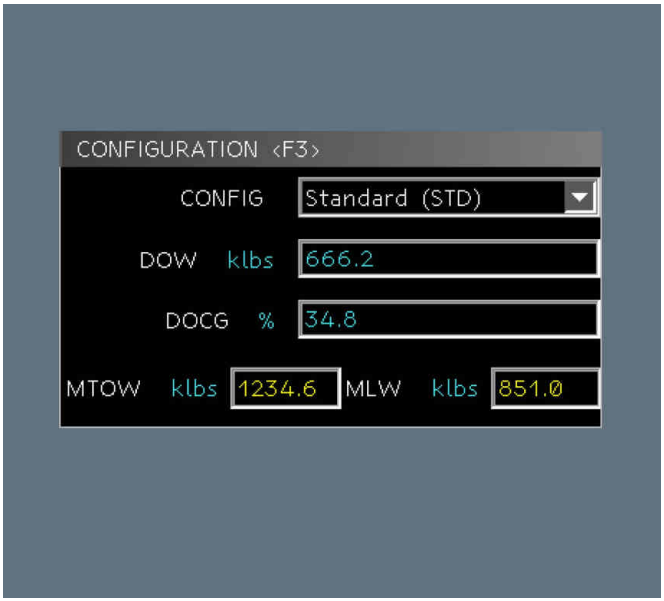
Note: After the computation, the DOW and DOCG values also appear on the RESULTS panel.

DOW/DOCG - "DIRECT DOW/CG IN REDUCED MODE" ENABLED

Applicable to: ALL

The flight crew directly enters the Dry Operating Weight (DOW) and the Dry Operating Center of Gravity (DOCG). The DOW and DOCG values appear in cyan.

CONFIGURATION Panel



Note: *After the computation, the DOW and DOCG values also appear on the RESULTS panel.*

MTOW

Applicable to: ALL

The MTOW field displays the weight that limits the loading. The MTOW is the minimum of:
- Maximum structural takeoff weight
- Maximum weight selected for the flight, in the case of multiple weight variants
- Maximum performance limited takeoff weight (MTOW(perf))
- MEL/CDL limited weight.

The flight crew can update the MTOW, but the weight cannot be above the Maximum Structural Takeoff Weight (MSTOW).

COMMUNICATION FROM T.O PERF TO LOADSHEET

When the MTOW value is displayed in yellow, it means that this value is retrieved from T.O PERF and corresponds to the MTOW(perf).

MLW

Applicable to: ALL

The MLW field displays the weight that limits the loading. The MLW is the minimum of:
- Maximum structural landing weight
- Maximum weight selected for the flight, in the case of multiple weight variants
- Maximum performance limited landing weight (MLW(perf))
- MEL/CDL limited weight.

The flight crew can update the MLW, but the weight cannot be above the Maximum Structural Landing Weight (MSLW).

COMMUNICATION FROM LDG PERF TO LOADSHEET

When the MLW value is displayed in yellow, it means that this value is retrieved from LDG PERF and corresponds to the MLW(perf).

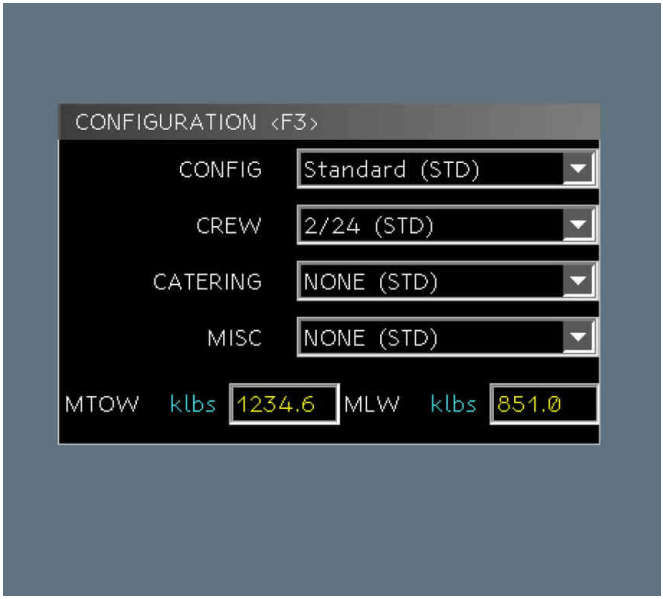
AIRCRAFT CONFIGURATION PANEL (DETAILED MODE ONLY)

Applicable to: ALL

The CONFIGURATION panel includes the following information:

- Configuration
- Crew (flight and cabin crew)
- Catering
- Miscellaneous Items
- MTOW
- MLW.

Aircraft Configuration Panel



CONFIGURATION

Applicable to: ALL

The CONFIG drop down list enables the flight crew to select the applicable configuration. The following parameters will automatically be updated accordingly:

- Basic Weight
- Passenger average weight
- Aircraft CG limits
- User interface.

If more than one configuration is defined, the flight crew must select the configuration that is applicable to the current flight.

CREW

Applicable to: ALL

The flight crew can select the applicable crew composition (flight crew and cabin crew). The crew composition weight is added to the aircraft basic weight contributing to DOW/CG calculation.

Note: *If CREW input is not available, a basic crew configuration is considered and the appropriate weight is included in the aircraft basic weight.*

CATERING

Applicable to: ALL

The flight crew can select the code corresponding to the catering currently loaded in the aircraft, or directly enter the catering weight per galley section. The catering weight is added to the aircraft basic weight contributing to DOW/CG definition.

MISCELLANEOUS ITEMS

Applicable to: ALL

Miscellaneous Items

If available, the flight crew can add the weight of any additional item (in addition to crew or catering) that needs to be taken into account in the DOW/CG calculation. The flight crew can select these items from a predefined list, or manually enter the weight and position of the item (e.g. H-arm). In this section, the flight crew can define up to 5 MISC items.

DOW/DOCG

Applicable to: ALL

The Dry Operating Weight (DOW) and the Dry Operating Center of Gravity (DOCG) are computed by adding the predefined basic weight of the aircraft to the flight crew input for flight and cabin crew, catering and miscellaneous items.
The DOW and DOCG values appear on the RESULTS panel.

MTOW

Applicable to: ALL

The MTOW field displays the weight that limits the loading. The MTOW is the minimum of:
- Maximum structural takeoff weight
- Maximum weight selected for the flight, in the case of multiple weight variants
- Maximum performance limited takeoff weight (MTOW(perf))
- MEL/CDL limited weight.

The flight crew can update the MTOW, but the weight cannot be above the Maximum Structural Takeoff Weight (MSTOW).

COMMUNICATION FROM T.O PERF TO LOADSHEET

When the MTOW value is displayed in yellow, it means that this value is retrieved from T.O PERF and corresponds to the MTOW(perf).

MLW

Applicable to: ALL

The MLW field displays the weight that limits the loading. The MLW is the minimum of:
- Maximum structural landing weight
- Maximum weight selected for the flight, in the case of multiple weight variants
- Maximum performance limited landing weight (MLW(perfo))
- MEL/CDL limited weight.

The flight crew can update the MLW, but the weight cannot be above the Maximum Structural Landing Weight (MSLW).

COMMUNICATION FROM LDG PERF TO LOADSHEET

When the MLW value is displayed in yellow, it means that this value is retrieved from LDG PERF and corresponds to the MLW(perf).

AIRCRAFT CONFIGURATION PANEL (REDUCED MODE PLUS DETAILED MODE) - "DIRECT DOW/CG IN DETAILED MODE" DISABLED

Applicable to: ALL

REDUCED ENTRY MODE

The CONFIGURATION panel includes the following information:
- Configuration
- Entry Mode
- DOW
- DOCG
- MTOW
- MLW.

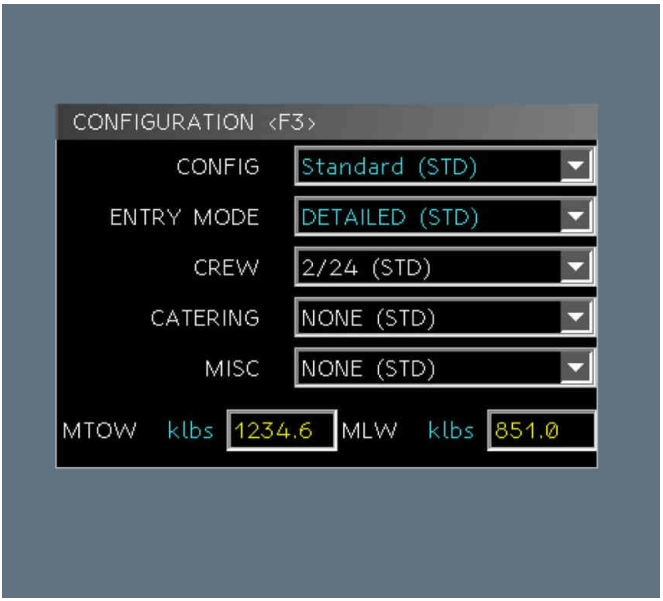
Aircraft Configuration Panel - REDUCED Entry Mode

DETAILED (STD) ENTRY MODE

The CONFIGURATION panel includes the following information:
- Configuration
- Entry Mode
- Crew (flight and cabin crew)

- Catering
- Miscellaneous Items
- MTOW
- MLW.

Aircraft Configuration Panel - DETAILED (STD) Entry Mode



AIRCRAFT CONFIGURATION PANEL (REDUCED MODE PLUS DETAILED MODE) - "DIRECT DOW/CG IN DETAILED MODE" ENABLED

Applicable to: ALL

REDUCED ENTRY MODE

The CONFIGURATION panel includes the following information:
- Configuration
- Entry Mode
- DOW
- DOCG
- MTOW
- MLW.

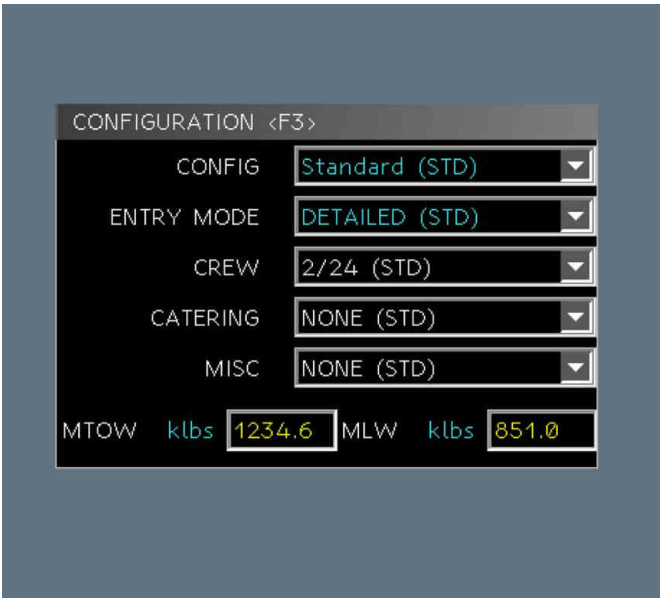
Aircraft Configuration Panel - REDUCED Entry Mode

DETAILED (STD) ENTRY MODE

The CONFIGURATION panel includes the following information:
- Configuration
- Entry Mode
- Crew (flight and cabin crew)

- Catering
- Miscellaneous Items
- MTOW
- MLW.

Aircraft Configuration Panel - DETAILED (STD) Entry Mode

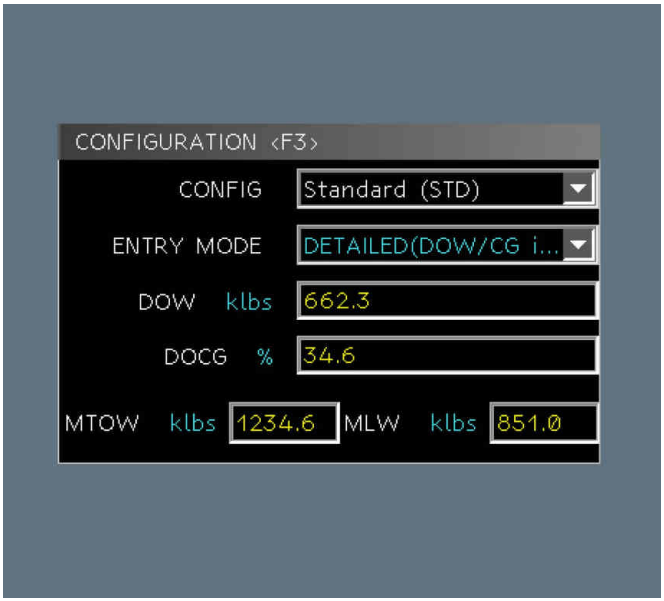


DETAILED (DOW/CG INPUT) ENTRY MODE

The CONFIGURATION panel includes the following information:

- Configuration
- Entry Mode
- DOW
- DOCG
- MTOW
- MLW.

Aircraft Configuration Panel - DETAILED (DOW/CG input) Entry Mode



CONFIGURATION

Applicable to: ALL

The CONFIG drop down list enables the flight crew to select the applicable configuration. The following parameters will automatically be updated accordingly:

- Basic Weight
- Passenger average weight
- Aircraft CG limits
- User interface.

If more than one configuration is defined, the flight crew must select the configuration that is applicable to the current flight.

ENTRY MODE

Applicable to: ALL

The flight crew can change from detailed to reduced mode, and vice versa.
When the flight crew changes the application from detailed mode to reduced mode, all data entered in the loadsheet that is related to payload and variable Operator items, is used to determine the ZFW/CG that will be displayed. However, when the flight crew changes back to detailed mode, data related to payload and variable Operator items is lost.

CREW

Applicable to: ALL

The flight crew can select the applicable crew composition (flight crew and cabin crew). The crew composition weight is added to the aircraft basic weight contributing to DOW/CG calculation.

Note: *If CREW input is not available, a basic crew configuration is considered and the appropriate weight is included in the aircraft basic weight.*

CATERING

Applicable to: ALL

The flight crew can select the code corresponding to the catering currently loaded in the aircraft, or directly enter the catering weight per galley section. The catering weight is added to the aircraft basic weight contributing to DOW/CG definition.

MISCELLANEOUS ITEMS

Applicable to: ALL

Miscellaneous Items

If available, the flight crew can add the weight of any additional item (in addition to crew or catering) that needs to be taken into account in the DOW/CG calculation. The flight crew can select these items from a predefined list, or manually enter the weight and position of the item (e.g. H-arm). In this section, the flight crew can define up to 5 MISC items.

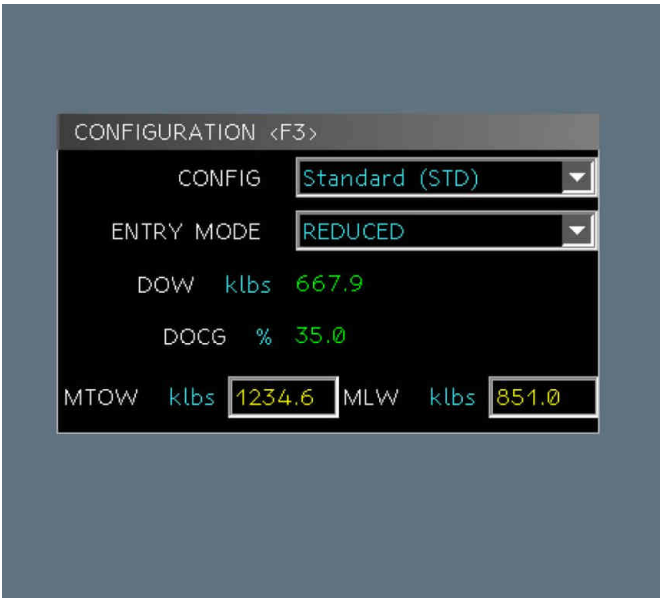
DOW/DOCG - "DIRECT DOW/CG IN DETAILED MODE" DISABLED

Applicable to: ALL

REDUCED ENTRY MODE

The DOW and DOCG fields display the default Dry Operating Weight (DOW) and the Dry Operating Center of Gravity (DOCG).

CONFIGURATION Panel - REDUCED Entry Mode

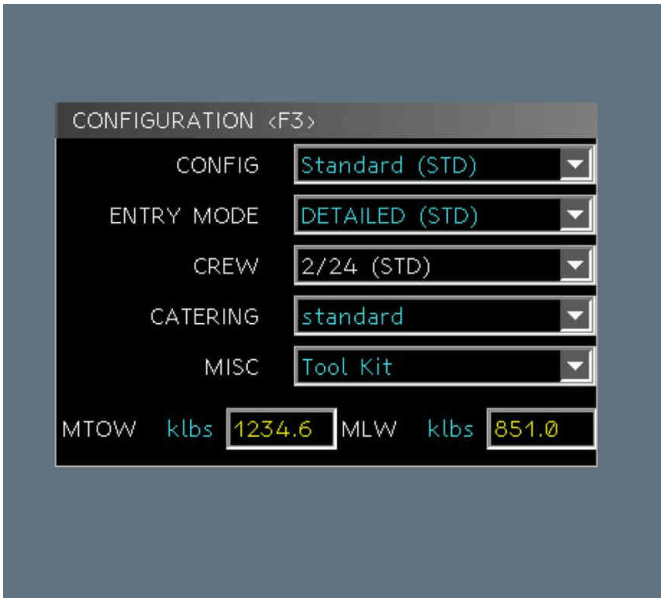


Note: *After the computation, the DOW and DOCG values also appear on the RESULTS panel.*

DETAILED (STD) ENTRY MODE

The Dry Operating Weight (DOW) and the Dry Operating Center of Gravity (DOCG) are computed by adding the predefined basic weight of the aircraft to the flight crew input for flight and cabin crew, catering and miscellaneous items.
The flight crew enters the crew composition, the catering and the additional loaded items part of the DOW/CG definition.

CONFIGURATION Panel - DETAILED (STD) Entry Mode



In order to obtain the DOW and DOCG values, the flight crew can:

- Start the computation, or
  After the computation, the DOW and DOCG values also appear on the RESULTS panel.
- Switch to the REDUCED entry mode. The DOW and DOCG values are automatically calculated using the data previously entered in the DETAILED (STD) Entry Mode. The values appear on the CONFIGURATION panel.

DOW/DOCG - "DIRECT DOW/CG IN DETAILED MODE" ENABLED

Applicable to: ALL

REDUCED ENTRY MODE

The DOW and DOCG fields display the default Dry Operating Weight (DOW) and the Dry Operating Center of Gravity (DOCG).

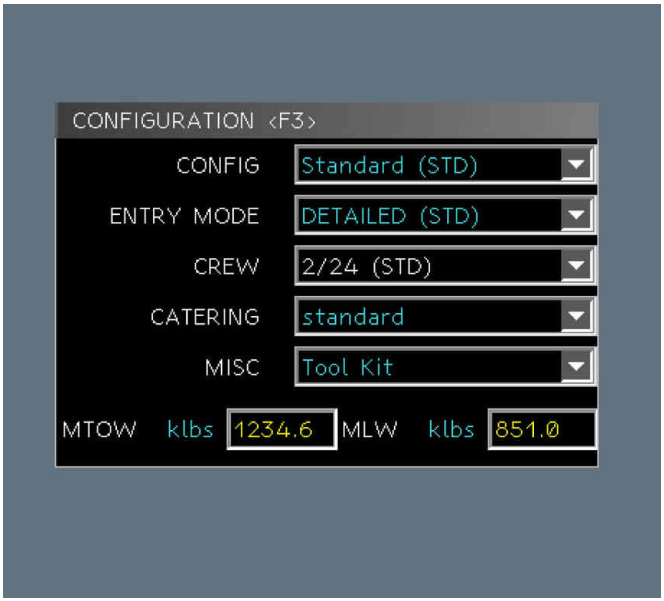
CONFIGURATION Panel - REDUCED Entry Mode

Note: *After the computation, the DOW and DOCG values also appear on the RESULTS panel.*

DETAILED (STD) ENTRY MODE

The Dry Operating Weight (DOW) and the Dry Operating Center of Gravity (DOCG) are computed by adding the predefined basic weight of the aircraft to the flight crew input for flight and cabin crew, catering and miscellaneous items.
The flight crew enters the crew composition, the catering and the additional loaded items part of the DOW/CG definition.

CONFIGURATION Panel - DETAILED (STD) Entry Mode



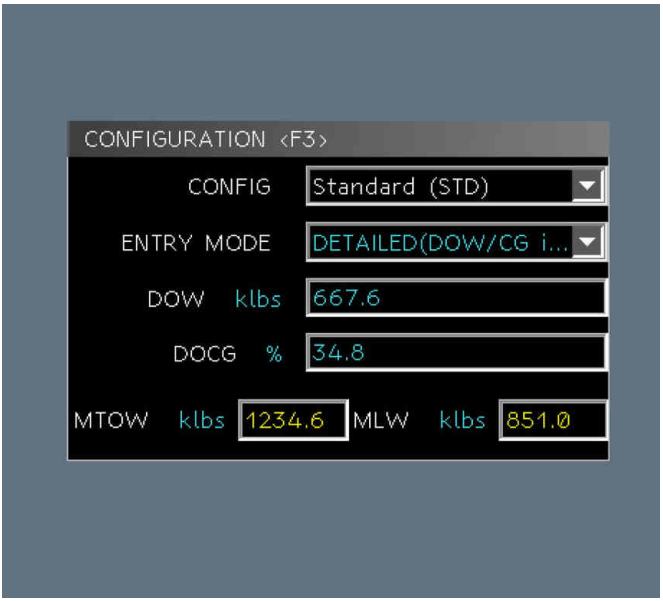
In order to obtain the DOW and DOCG values, the flight crew can:

- Start the computation, or
  After the computation, the DOW and DOCG values also appear on the RESULTS panel.
- Switch to the REDUCED entry mode. The DOW and DOCG values are automatically calculated using the data previously entered in the DETAILED (STD) Entry Mode. The values appear on the CONFIGURATION panel.

DETAILED (DOW/CG INPUT) ENTRY MODE

The flight crew directly enters the Dry Operating Weight (DOW) and the Dry Operating Center of Gravity (DOCG), without setting the crew code, the catering or miscellaneous items. In this case, the values appear in cyan.

CONFIGURATION Panel - DETAILED(DOW/CG input) Entry Mode



MTOW

Applicable to: ALL

The MTOW field displays the weight that limits the loading. The MTOW is the minimum of:
- Maximum structural takeoff weight
- Maximum weight selected for the flight, in the case of multiple weight variants
- Maximum performance limited takeoff weight (MTOW(perf))
- MEL/CDL limited weight.

The flight crew can update the MTOW, but the weight cannot be above the Maximum Structural Takeoff Weight (MSTOW).

COMMUNICATION FROM T.O PERF TO LOADSHEET

When the MTOW value is displayed in yellow, it means that this value is retrieved from T.O PERF and corresponds to the MTOW(perf).

MLW

Applicable to: ALL

The MLW field displays the weight that limits the loading. The MLW is the minimum of:

- Maximum structural landing weight
- Maximum weight selected for the flight, in the case of multiple weight variants
- Maximum performance limited landing weight (MLW(perfo))
- MEL/CDL limited weight.

The flight crew can update the MLW, but the weight cannot be above the Maximum Structural Landing Weight (MSLW).

COMMUNICATION FROM LDG PERF TO LOADSHEET

When the MLW value is displayed in yellow, it means that this value is retrieved from LDG PERF and corresponds to the MLW(perf).

Intentionally left blank

PAYLOAD DATA (REDUCED MODE)

Applicable to: ALL

Payload Data

ZFW/CG

The flight crew must enter the ZFW and ZFCG .

LMC

The flight crew can enter the LMC .
For more information about the LMC , *Refer to PER-LOD-LAI-PRM Last Minute Changes (LMC)* .

LAST MINUTE CHANGES (LMC)

Applicable to: ALL

In the case of Last Minute Changes (LMC), the flight crew can enter the increment or decrement in passenger number or cargo weight, in the LMC panel.

The flight crew can enter LMC either:

- In the corresponding cabin section or cargo compartment. In this case, all the weights and corresponding CGs (ZFCG, TOCG, LDCG) are automatically updated

L2 LMC weight limited in this case by underload and operational CG envelopes.

L1 - Or, as a total LMC. In this case, only the weights are automatically updated.

L2 LMC weight limited in this case by underload and maximum LMC tolerance.

L1 *Note: A maximum value for LMC in the passenger or cargo section is predefined in the loadsheet application, as per Operator's policy.*

PAYLOAD DATA (DETAILED MODE)

Applicable to: ALL

Payload Data

LOADING SECTION

The flight crew must enter the payload loading including:
- Pax
- Cargo.

For more information about the loading, *Refer to PER-LOD-LAI-PDM Payload Loading Section* .

DISTRIBUTION SECTION

The flight crew can enter the payload distribution for:
- Passengers
- Cargo.

For more information about the distribution, *Refer to PER-LOD-LAI-PDM Payload Distribution Section* .

PAYLOAD LOADING SECTION

Applicable to: ALL

PASSENGER

The flight crew must enter the number of passengers by passenger type (e.g.: Adult/Child/Infant). For each passenger type, a corresponding weight is defined as per Operator's policy (e.g. Adults: 185 lb / Children: 77 lb / Infants: 22 lb).

Note: Some passengers (e.g. infants) can be defined as not occupying a seat. Passengers that do not occupy a seat are disregarded for the passenger count, when checking that capacity in the cabin is not exceeded.

CARGO

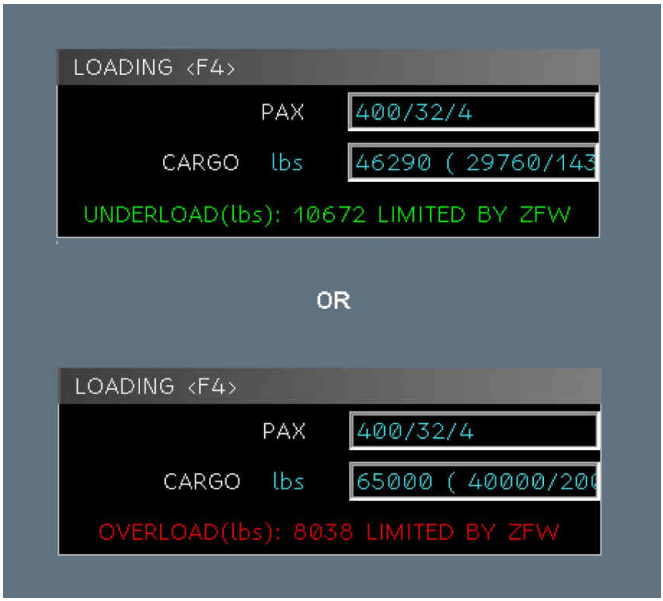
The flight crew must enter the cargo weight by cargo type (e.g.: Cargo/Baggage/Mail).

Note: It may be possible to set the amount of some cargo type(s) (e.g. baggage) by number of pieces. For each cargo type, the corresponding weight of the item is predefined.

UNDERLOAD / OVERLOAD

When the flight crew enters information in the loading panel, the corresponding underload is computed and displayed in green on the loading panel. The name of the aircraft maximum weight limiting the underload is also displayed (MZFW, MLW, MTOW). If the underload is negative, it is displayed as overload in red.

LOADING Panel



PAYLOAD DISTRIBUTION SECTION

Applicable to: ALL

PASSENGER

The flight crew can distribute passengers in the cabin sections, or can enter a total number of passengers.

Input can be made:
- By type of passenger, as defined in the LOADING panel PAX field. In this case each corresponding passenger weight is taken into account.
- By total number of passengers. In this case an average weight per passenger is computed in the LOADING panel, depending on the number of passenger in each passenger type group.

Note: *If both entries are available, the flight crew can change from one input to another via a toggle button.*

The TOTAL field displays the passengers already loaded in the distribution section.
The ΔPAX field contains the difference between the number of passengers entered in the loading section, and passengers that are already distributed (in TOTAL field).

Note: *If the number of loaded passengers in the distribution section exceeds the number of passengers entered in the loading section, the ΔPAX indication appears in red and the number of extra passenger(s) is indicated.*

CARGO

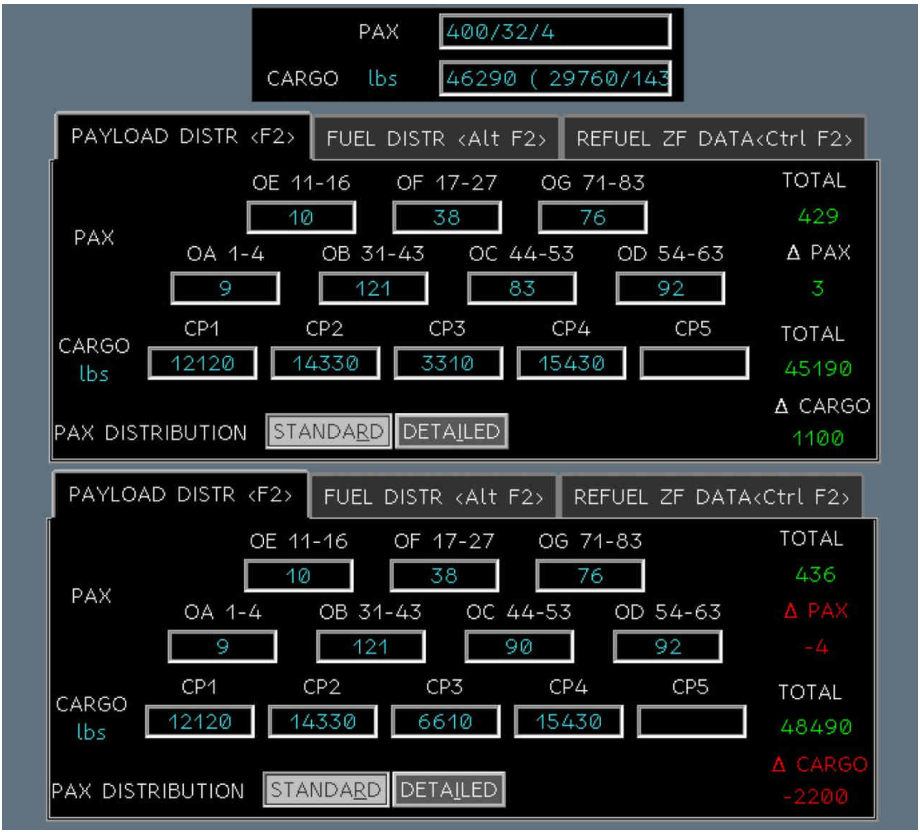
The flight crew must distribute the total weight of cargo between the cargo compartments defined for the aircraft. The flight crew can enter input per cargo compartment, either by cargo type, as defined in the LOADING panel, or by total cargo weight.

Note: *The flight crew may use both input types simultaneously, as required.*

The TOTAL field displays the cargo weight that is already loaded in the distribution section.
The ΔCARGO field contains the difference between the cargo weight entered in the loading section, and the cargo that is already distributed (in TOTAL field).

Note: *If the loaded cargo weight in the distribution section exceeds the cargo weight entered in the loading section, the ΔCARGO indication appears in red and the extra weight is indicated.*

Payload Distribution

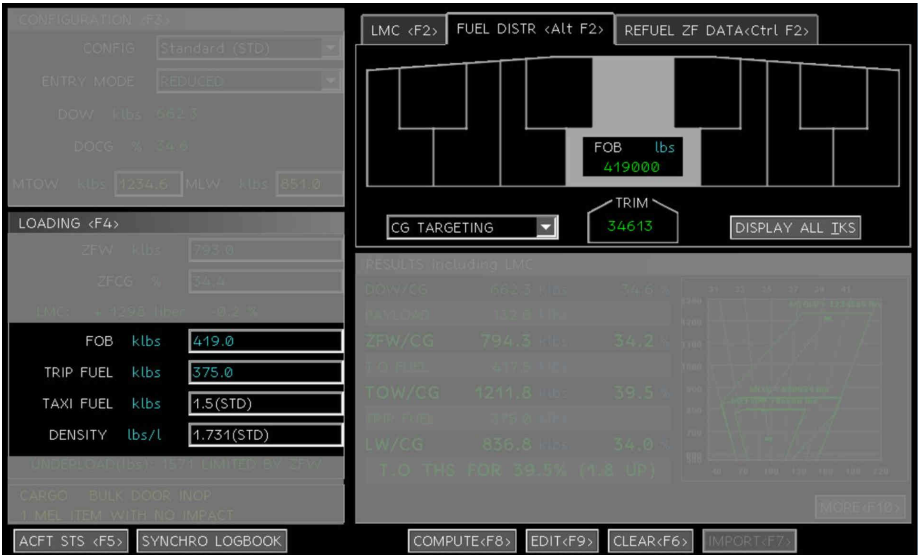


Intentionally left blank

FUEL DATA

Applicable to: ALL

Fuel Data



LOADING SECTION

The flight crew must enter the following fuel quantities:

- Fuel On Board (FOB)
- Trip fuel
- Taxi fuel, if necessary
- Fuel density, if necessary.

For more information about the fuel, *Refer to PER-LOD-LAI-FUL Fuel Loading Section* .

FUEL DISTRIBUTION SECTION

The flight crew can access the predicted fuel distribution or enter the fuel distribution.
For more information about the fuel distribution, *Refer to PER-LOD-LAI-FUL Fuel Distribution Section* .

REFUEL ZF DATA

The flight crew can access and modify the ZFW / CG used by the loadsheet application for fuel distribution computation.

For more information about the refuel ZF data, *Refer to PER-LOD-LAI-FUL REFUEL ZF DATA Panel* .

FUEL LOADING SECTION

Applicable to: ALL

FOB

The flight crew can enter the Fuel On Board (FOB) for Gross Weight (GW) computation. The FOB is equal to the Ramp Fuel.
The FOB corresponds either to the Preselected Fuel Quantity (PFQ) or to the actual FOB that appears on the FUEL SD page. The FOB is also used with taxi fuel to estimate the fuel distribution per tank at takeoff, and the TOCG.

Note: *Loadsheet computations fail when the flight crew enters the maximum FOB for the aircraft.*
Workaround: Reduce the FOB by 350 lb.

TRIP FUEL

The flight crew can enter the estimated trip fuel for LW computation. Trip fuel is also used to estimate the fuel distribution per tank at landing, and the LDCG.

TAXI FUEL

If the taxi fuel field is available, the flight crew can enter the estimated taxi fuel. The application subtracts taxi fuel from the entered FOB in order to compute the TOW.
If the flight crew is not able to modify the taxi fuel, a standard value is used.

FUEL DENSITY

If the fuel density field is available, the flight crew can enter the fuel density. The fuel density is used to compute fuel distribution per tank.
If the flight crew is not able to modify the fuel density, a standard value is used.

FUEL DISTRIBUTION SECTION

Applicable to: ALL

The loadsheet application enables the flight crew to determine the effect of the fuel distribution, per tank, on the aircraft's CG .
Fuel distribution is either a result of computation, or a flight crew input that is displayed on the ECAM .

The FUEL DISTR panel enables the flight crew to:

- Either visualize predicted fuel distribution after refuelling in accordance with the Fuel Quantity and Management System (FQMS) CG targeting logic

L2 For more information about the FQMS CG targeting logic, *Refer to Aircraft Systems - CG Targeting* .

L1 , or

- Set a fuel distribution as per ECAM FUEL PAGE information, in order to recompute the corresponding TOW / CG .

The flight crew can select the requested visualization mode, using the ALL TANKS/TRIM TK ONLY button on the FUEL DISTR panel. By default, only FOB and trim tank fuel quantity are visible.

The flight crew can select between three types of computation, using the drop-down list on the FUEL DISTR panel:

- CG TARGETING: No input from the flight crew is required

L2 For more information about CG targeting, *Refer to PER-LOD-FDC-CGT CG Targeting* .

L1 <u>Note:</u> *If the flight crew performs a CG TARGETING computation, the fuel tank fields are set to the predicted fuel quantity. As a result, when the flight crew changes the drop-down list to TRIM ADJUSTMENT or MANUAL DISTR, all fields are predefined.*

- TRIM ADJUSTMENT: The flight crew is requested to set the trim tank fuel quantity as per ECAM FUEL PAGE information

L2 For more information about trim adjustment, *Refer to PER-LOD-FDC Trim Tank Adjustment* .

L1 <u>Note:</u> *In TRIM ADJUSTMENT mode, if trim tank fuel quantity is modified, the other fuel tank fields are emptied, because the wing fuel distribution needs to be recomputed.*

- MANUAL DISTR: The flight crew is requested to set tank fuel quantities as per ECAM FUEL PAGE information. When the flight crew modifies the fuel tank quantities, the distribution section FOB is automatically recomputed. Loading and distribution sections FOB values can differ within a tolerance, as per Operator policy.

L2 For more information about manual distribution, *Refer to All tank fuel quantities manual input* .

L1 *Note: In the case of a manual fuel distribution, the sum of all tanks (distribution section FOB) must be exactly identical to the total FOB (loading section FOB): there is no tolerance.*

REFUEL ZF DATA PANEL

Applicable to: ALL

REFUEL ZF DATA panel enables to define ZFW and ZFCG values to be used for the computation of the predicted fuel distribution after refuelling as per FQMS CG targeting logic.

L2 For more information about the FQMS CG targeting logic, *Refer to Aircraft Systems - CG Targeting* .

L1 The flight crew can set ZFW / CG :

- To the default refuel values, using the FQMS DEFAULT button on the REFUEL ZF DATA panel. These values correspond to the values used by the FQMS in order to determine the aircraft fuel distribution in the case no ZFW / CG data has been inserted in the system before refuelling was started

L2 For more information about the default ZFW / CG values, *Refer to Aircraft Systems - CG Targeting* .

L1 - To predefined values, using the NEW SET OF DATA button. The flight crew manually enters these values, which should correspond to the values entered into the FQMS before refuelling was started
- To the values computed in the application from the loading entries, using the LOADSHEET button.

The values that the flight crew selects will have an impact on the fuel distribution per tank computation in CG TARGETING mode.

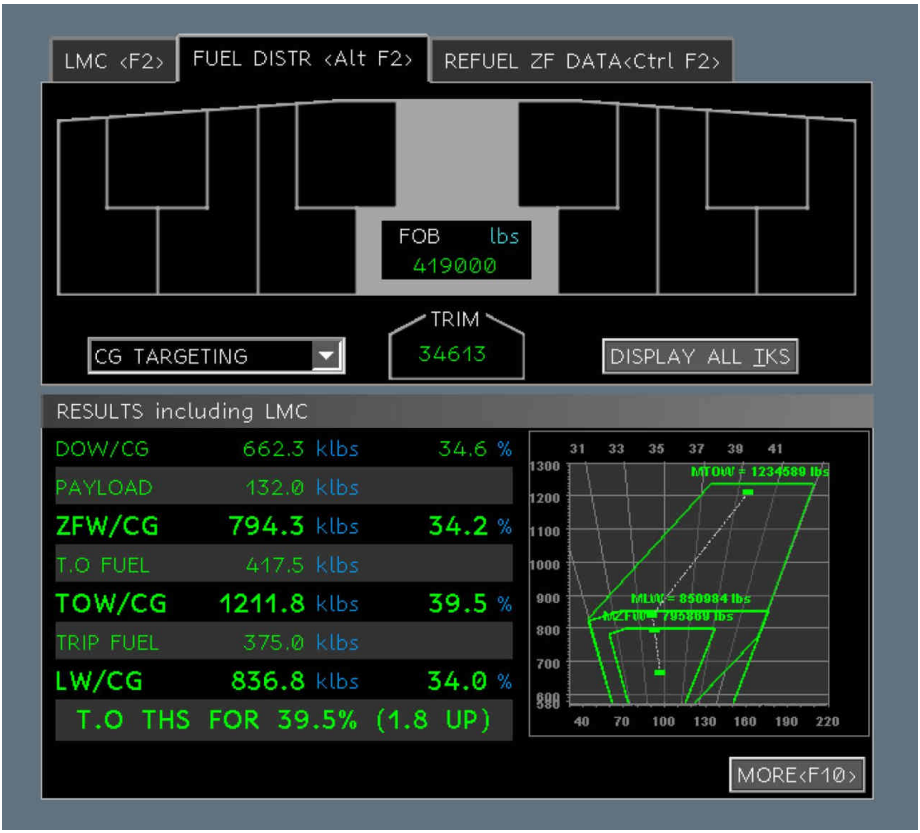
RESULTS PANEL

Applicable to: ALL

The flight crew can access, via the RESULTS panel:

- Basic loading results
- Fuel distribution
- Detailed results and Automatic Ground Transfer (AGT) information, using the MORE button on the RESULTS panel.

RESULTS Panel

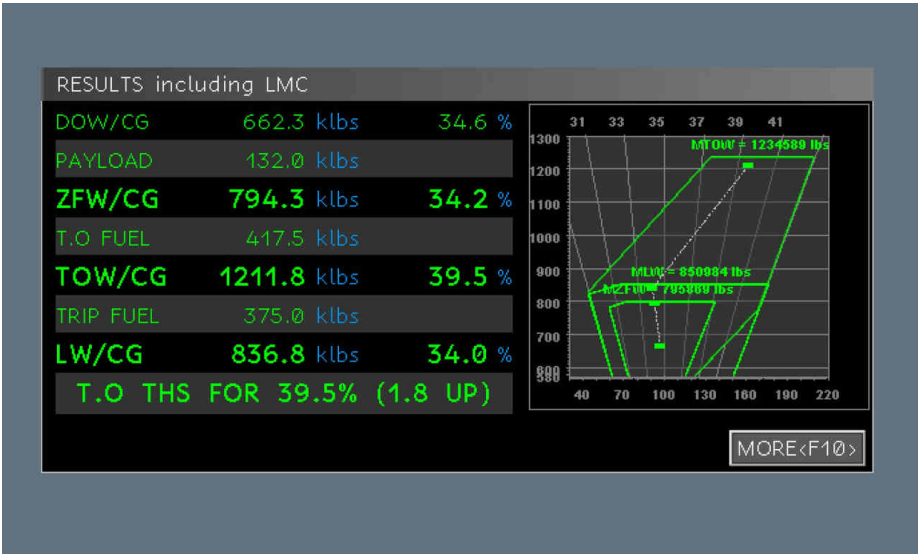


BASIC RESULTS

Applicable to: ALL

After a computation, the following results are displayed on the RESULTS panel:

Basic Results



DOW/CG

- In DETAILED (STD) mode, the DOW / CG values are computed by adding the predefined basic weight of the aircraft to the flight crew input for the flight and cabin crew, the catering and the miscellaneous items
- In DETAILED(DOW/CG input) mode, the DOW / CG values are equal to the values entered by the flight crew in the DOW and DOCG fields of the CONFIGURATION panel.
- In REDUCED mode, the DOW / CG values are equal to:
  - The default DOW and DOCG values, or
  - The values entered by the flight crew in the DOW and DOCG fields of the CONFIGURATION panel, if the DOW and DOCG fields are enabled as per Operator policy.

PAYLOAD

- In DETAILED mode, payload is computed as the sum of passengers and cargo weights
- In REDUCED mode, payload is the difference between ZFW and DOW .

ZFW/CG

If the ZFW / CG is not within the corresponding limits, the ZFW / CG values appear in red and the flight crew cannot access the LTS EDITION panel.

T.O FUEL

T.O FUEL value corresponds to FOB decreased by taxi fuel weight.

TOW/CG

If the TOW / CG is not within the corresponding limits, the TOW / CG values appear in red and the flight crew cannot access the LTS EDITION panel. The flight crew must perform an AGT to move the CG back in the limits, if possible. The flight crew can use the MORE panel to have more information about the quantity of fuel to transfer to move the CG back in the limits or to move the CG back on the refueling target.

L2 For more information about AGT , *Refer to Aircraft Systems - Automatic Ground Transfer* .

L1 **COMMUNICATION FROM LOADSHEET TO T.O PERF**

When the flight crew changes from LOADSHEET to T.O PERF, LOADSHEET transfers the calculated TOW value to T.O PERF. T.O PERF displays this value in yellow in the CONDITIONS panel.

TRIP FUEL

Trip fuel is the weight of fuel predicted to be burned during the trip, without taking into account the reserve fuel.

LW/CG

If the LW / CG is not within the corresponding limits, the LW / CG values appear in red and the flight crew cannot access the LTS EDITION panel.

COMMUNICATION FROM LOADSHEET TO LDG PERF

When the flight crew changes from LOADSHEET to LDG PERF, LOADSHEET transfers the calculated LW value to LDG PERF. LDG PERF displays this value in yellow in the CONDITIONS panel.

T.O THS FOR

The T.O THS FOR value is the takeoff trim setting that depends on the TOW / CG .

CG POSITIONS GRAPHICAL PRESENTATION

The CG diagram indicates all CG points DOW / CG , ZFW / CG , LW / CG , TOW / CG and also the corresponding CG limits (ZF , LDG , T.O).

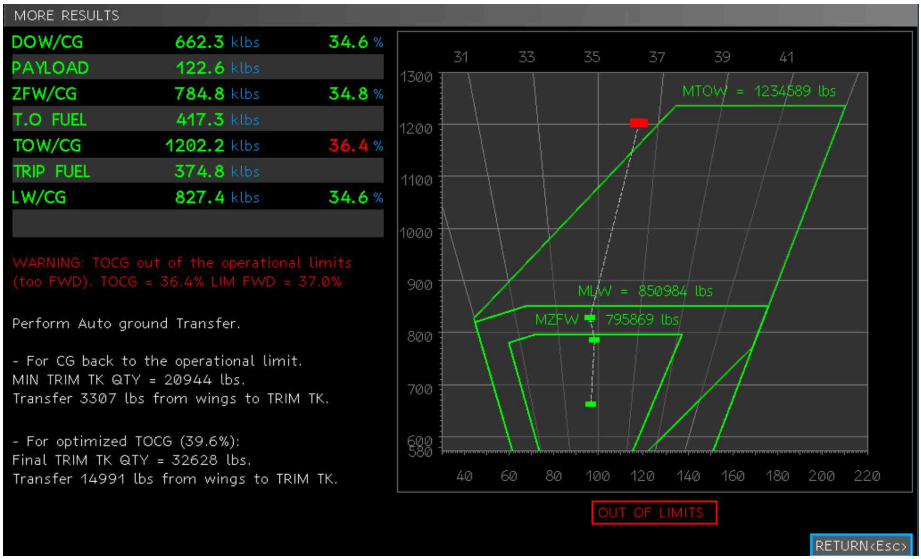
MORE PANEL & AGT INFORMATION

Applicable to: ALL

The flight crew can access the MORE panel by pressing the MORE button on the RESULTS panel.
The MORE panel includes the primary outputs, as well as a larger version of the CG diagram.
If TOCG is not within operational limits, a warning appears on the MORE panel, indicating the value of the calculated TOCG, and the value of the limit TOCG corresponding to TOW.

The following information on AGT appears on the MORE panel:
- The amount of fuel to be transferred to move the CG back in the limits
- The amount of fuel to be transferred to move the CG back on the refuelling target.

MORE Panel & AGT Information



FUEL DISTRIBUTION

Applicable to: ALL

The FUEL DISTR panel enables the flight crew to access the fuel distribution per tank, in accordance with the FQMS logic.

L2 For more information about the FQMS CG targeting logic and fuel distribution, *Refer to Aircraft Systems - CG Targeting* .

L1 The flight crew can access two different types of results, depending on the computation mode selected by the flight crew:

- CG TARGETING: The FUEL DISTR panel displays the predicted fuel quantity in the trim tank after a CG targeting process. The ALL TANKS button enables to display the predicted fuel distribution in the other tanks

L2 For more information about CG targeting, *Refer to PER-LOD-FDC-CGT CG Targeting* .

L1 - TRIM ADJUSTMENT: If the flight crew selects ALL TANKS, the FUEL DISTR panel displays the predicted fuel distribution in the wing tanks, corresponding to the standard refuelling logic, taking into account the flight crew trim tank fuel quantity input.

L2 For more information about trim adjustment, *Refer to PER-LOD-FDC Trim Tank Adjustment* .

Intentionally left blank

REPORT PANEL (REDUCED MODE)

Applicable to: ALL

Report Panel

ADDITIONAL INPUT

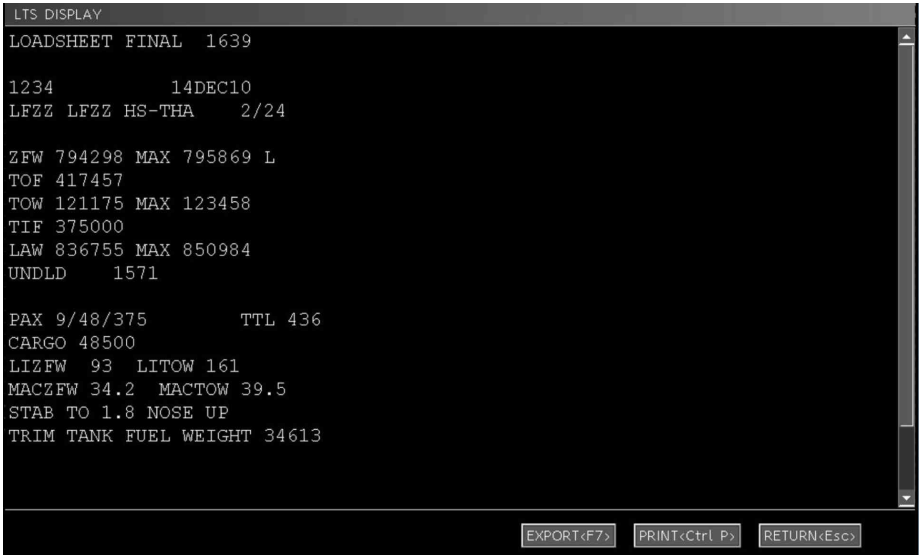
The flight crew enters additional input requested to appear on the loadsheet, and additional information entered by the Captain in the CAPT INFO NOTES frame (limited to 5 lines of text).

REDUCED LOADSHEET

The flight crew can generate a reduced loadsheet, corresponding to the AHM518 IATA format (ACARS Loadsheet).
A status has to be set for the generated loadsheet: PRELIM or FINAL.

LTS DISPLAY

LTS DISPLAY



When the loadsheet is generated, the flight crew can:

- Send the loadsheet to the ground,
- Print the loadsheet, in order to sign it manually, if necessary.

Note: After any of these actions, the loadsheet is also stored in the Electronic Flight Folder (EFF), if installed.

REPORT PANEL (DETAILED MODE)

Applicable to: ALL

Report Panel

ADDITIONAL INPUT

The flight crew enters additional input requested to appear on the loadsheet, and additional information entered by the Captain in the CAPT INFO NOTES frame (limited to 5 lines of text).

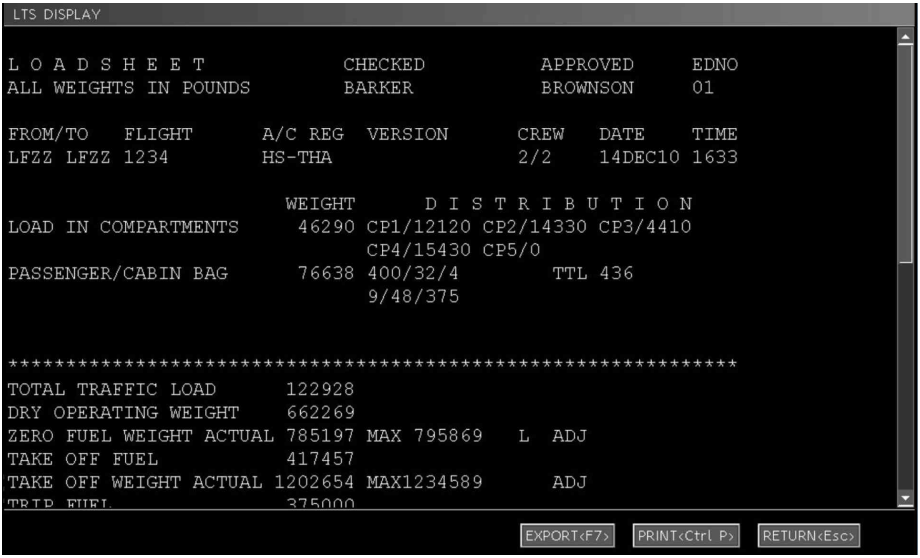
DETAILED OR REDUCED LOADSHEET

The flight crew can generate:

- A detailed loadsheet, corresponding to the AHM517 IATA format, or
  The flight crew must set an edition number in the ED N° drop-down list, if several loadsheets are generated consecutively, in order to follow-up the last version.
- A reduced loadsheet, corresponding to the AHM518 IATA format (ACARS Loadsheet).
  A status has to be set for the generated loadsheet: PRELIM or FINAL.

LTS DISPLAY

LTS DISPLAY



When the loadsheet is generated, the flight crew can:

- Send the loadsheet to the ground,
- Print the loadsheet, in order to sign it manually, if necessary.

Note: After any of these actions, the loadsheet is also stored in the Electronic Flight Folder (EFF), if installed.

CG TARGETING

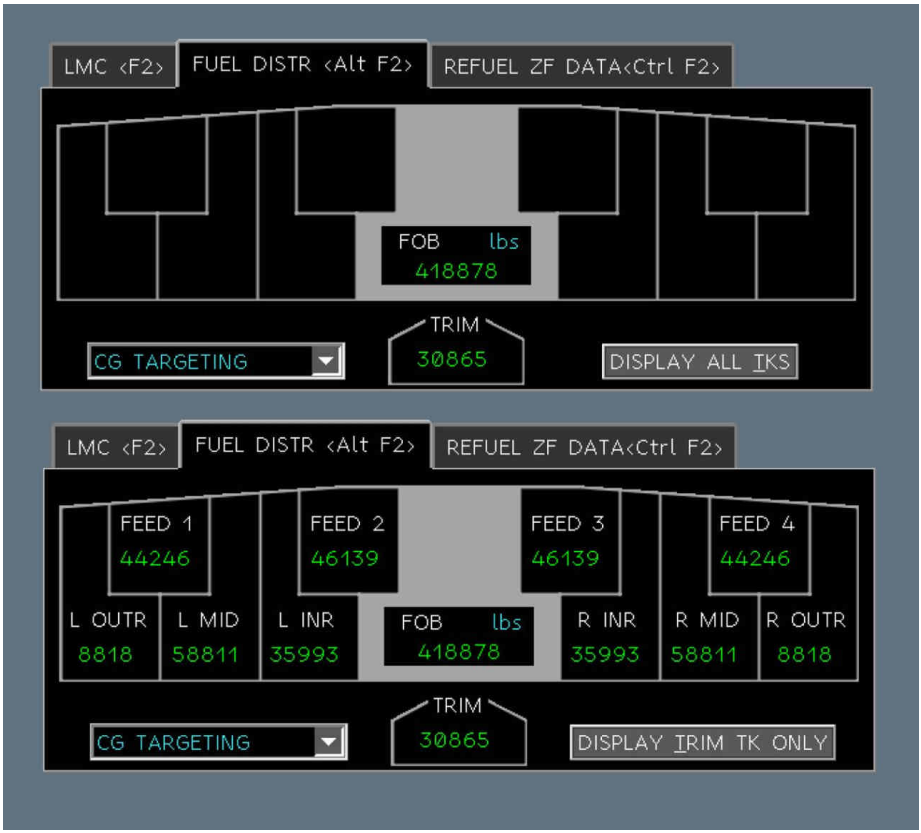
Applicable to: ALL

The CG targeting computation reflects the FQMS logic, and therefore requires the following three entries:

- Fuel On Board (FOB)
- ZFW, used during the refuelling process
- ZFCG, used during the refuelling process.

The flight crew enters these data via the LOADING panel and the REFUEL ZF DATA panel.
The output is then TOW/CG and either the corresponding fuel quantity in the trim tank or the fuel distribution in all tanks, depending on the level of detail requested by the flight crew.

CG Targeting



TRIM TANK ADJUSTMENT

Applicable to: ALL

The trim tank adjustment computation is based on the knowledge of the total FOB and the trim tank fuel quantity value. The trim tank adjustment computation is used to compute TOW/CG if the ZFW/CG used for refuel is not available, or if there is a discrepancy between the ECAM GW/CG and the computed TOW/CG.

The flight crew must enter the fuel loading data and the actual trim tank fuel quantity displayed on the ECAM FUEL page.

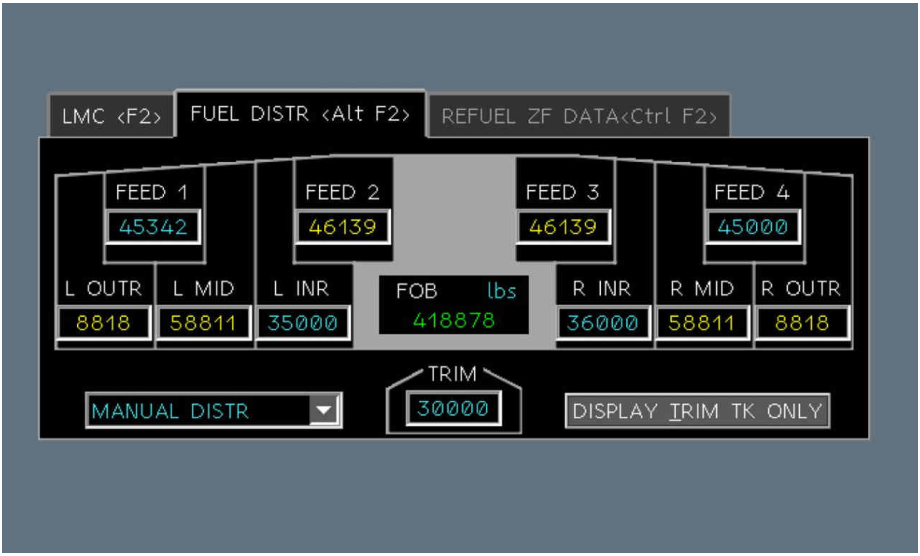
Trim Tank Adjustment

ALL TANK FUEL QUANTITIES MANUAL INPUT

Applicable to: ALL

The all tank fuel quantities manual input computation is based on the knowledge of all tank fuel quantity values. The all tank fuel quantities manual input is used to compute TOW/CG if fuel distribution is not standard. LW/CG is also computed from the additional input trip fuel.

Manual Distribution



AIRCRAFT STATUS PANEL

Applicable to: ALL

The current aircraft status must be considered during flight preparation.

The reminder area of the AIRCRAFT STATUS panel lists:
- MEL items impacting loading capabilities
- The number of MEL items without loading capabilities impact (if any).

If the aircraft is dispatched without any deferred items, "NORMAL" appears in the reminder area of the AIRCRAFT STATUS panel.

Reminder area of the AIRCRAFT STATUS Panel

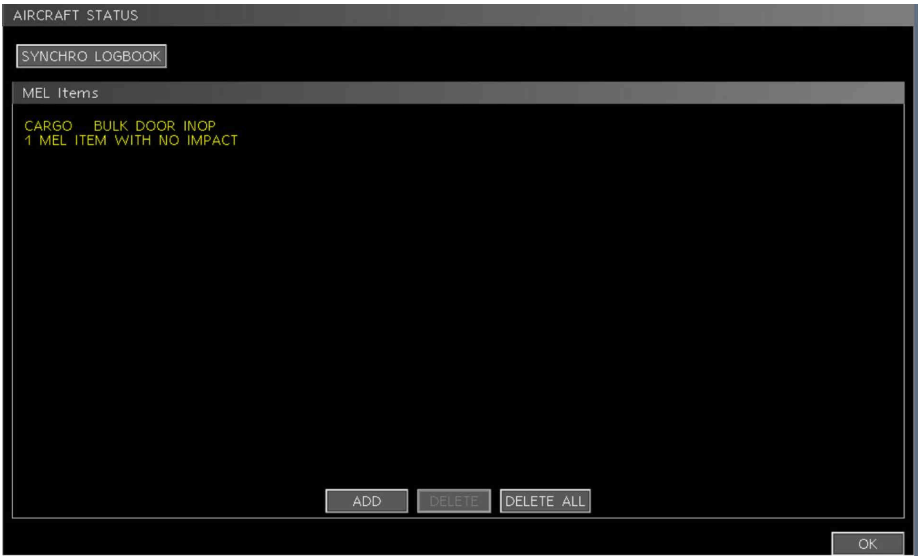
SYNCHRO LOGBOOK

The flight crew can recover the eLogbook status by clicking on the "SYNCHRO LOGBOOK" button.
For more information about the SYNCHRO LOGBOOK function, *Refer to PER-LOD-ACS Synchronization with Logbook* .

AIRCRAFT STATUS

By clicking on the ACFT STS button, the flight crew opens the AIRCRAFT STATUS panel.
The AIRCRAFT STATUS panel has one subpanel: MEL Items.
Moreover, the flight crew can recover the eLogbook status by clicking on the "SYNCHRO LOGBOOK" button.

AIRCRAFT STATUS Panel



MEL

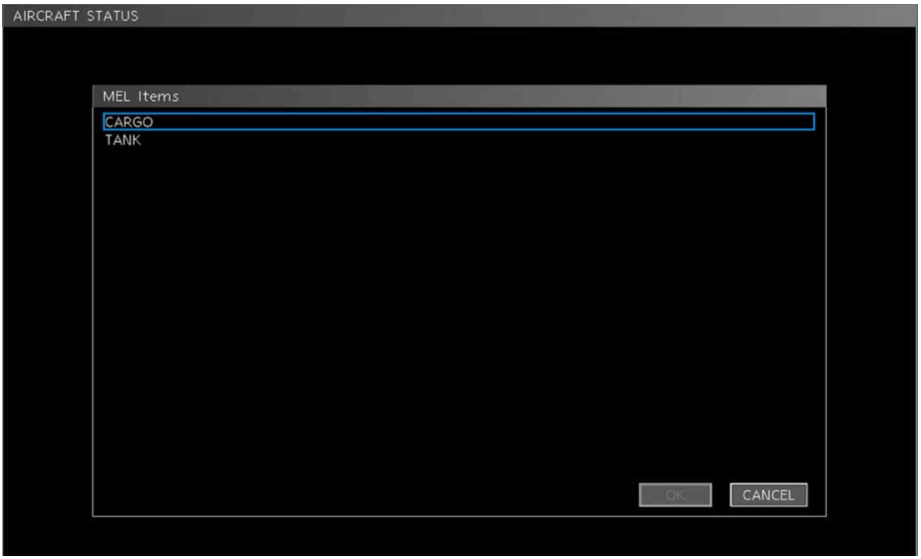
Applicable to: ALL

The MEL items subpanel displays the inoperative systems selected by the flight crew using:
- The OPS LIBRARY / MEL manual, via the selection of a MEL item, or
  In this case, the inoperative systems are displayed in yellow on Loadsheet Application.
- The Loadsheet Application MEL panel.
  In this case, the MEL items are displayed in cyan on Loadsheet Application.

By clicking on the ADD button of the MEL items subpanel, the flight crew opens the MEL items panel. The MEL items panel displays the list of MEL items that may impact loading capabilities.

These MEL items may have an impact on:
- Fuel
- Characteristics
- Weights
- Envelopes
- DOW
- Cabin
- Compartment.

MEL Items Panel



The flight crew selects a MEL item by first selecting the applicable system, and then the corresponding MEL item.
Items selected from the lists on the MEL items panel appear in the MEL items subpanel and in the reminder area of the AIRCRAFT STATUS panel.

Note: *If the flight crew selects a MEL item with an impact on Fuel Distribution, the associated non standard fuel distribution is not computed.*
Workaround: The flight crew shall use the Manual Distribution function with fuel quantities read on the ECAM.

COMMUNICATION BETWEEN MEL MANUAL AND LOADSHEET APPLICATION

When the aircraft is dispatched with MEL items and if these MEL items are selected via the OPS LIBRAY / MEL manual:

- The associated MEL items impacting loading capabilities are automatically selected and displayed in yellow on the reminder area of the AIRCRAFT STATUS panel in Loadsheet Application
- The number of MEL items without loading performance impact is displayed in yellow on the reminder area of the AIRCRAFT STATUS panel in Loadsheet Application.

SYNCHRONIZATION WITH LOGBOOK

Applicable to: ALL

The flight crew can recover the eLogbook status by clicking on the "SYNCHRO LOGBOOK" button. This action synchronizes the aircraft status of the whole FLT OPS domain with the current deferred items of the eLogbook
If the flight crew had previously selected additional MEL items in Loadsheet Application (displayed in cyan in the AIRCRAFT STATUS panel) and then uses the SYNCHRO LOGBOOK function, these manually entered items are lost.

Note: *When the flight crew uses the SYNCHRO LOGBOOK function in Loadsheet Application, the whole FLT OPS domain is also synchronized with the eLogbook.*

MAXIMUM TAKEOFF

Applicable to: ALL

The “Maximum Takeoff” thrust rating is the maximum thrust certified for takeoff and is normally limited to 5 min .
This time is extended to 10 min for engine out contingency, as authorized by the approved AFM .

The FADEC commands the “Maximum Takeoff” thrust rating:

- For a thrust lever on the TOGA detent
- Up to the throttle reduction.

L2 In fact, once throttle reduction achieved, if the PF moves back the thrust lever to TOGA , the corresponding thrust rating is the “Maximum Go Around” one.
For more information about the “Maximum Go Around” thrust rating, *Refer to PER-THR-NRM-MGA Maximum Go Around* .

DERATED TAKEOFF

Applicable to: ALL

The “Derated Takeoff” thrust rating is a reduced maximum thrust certified for takeoff.
For detailed information about the “Derated Takeoff” thrust rating, *Refer to PER-TOF-THR-DRT Definition of Derated Takeoff* .

The FADEC commands the “Derated Takeoff” thrust rating:

- For a thrust lever on the FLX / MCT detent, with a derate level entered into the MFD - PERF - TO page
- Up to a throttle reduction or a TOGA recovery.

L2 In fact, after the throttle reduction or the TOGA recovery, if the PF moves back the thrust lever to FLX / MCT , the corresponding thrust rating is the “Maximum Continuous” one.
For more information about the “Maximum Continuous” thrust rating, *Refer to PER-THR-NRM-MCT Maximum Continuous* .

FLEXIBLE TAKEOFF

Applicable to: ALL

The “Flexible Takeoff” thrust rating is a reduced takeoff thrust as compared to the maximum permissible one.

The related THR is calculated as a function of the flexible temperature (TFLEX) entered in the MFD .

TFLEX is a function of the aircraft weight and environmental conditions.

It guarantees that the regular performance requirements are met.

L2 For detailed information about FLEX Takeoff, *Refer to PER-TOF-THR-FLX Definition of FLEX Takeoff* .

L1 The FADEC commands the “Flexible Takeoff” thrust rating:

- For a thrust lever on the FLX / MCT detent, with a TFLEX entered into the MFD - PERF - TO page
- Up to the throttle reduction or a TOGA recovery.

L2 In fact, after the throttle reduction or the TOGA recovery, if the PF moves back the thrust lever to FLX / MCT , the corresponding thrust rating is the “Maximum Continuous” one.

For more information about the “Maximum Continuous” thrust rating, *Refer to PER-THR-NRM-MCT Maximum Continuous* .

MAXIMUM GO AROUND

Applicable to: ALL

The "Maximum Go Around" thrust rating is the maximum permissible thrust during go-around.

The FADEC commands the "Maximum Go Around" thrust rating:
- For a thrust lever on the TOGA detent
- After the throttle reduction
- Below 14 500 ft.

MAXIMUM CONTINUOUS

Applicable to: ALL

The “Maximum Continuous” thrust rating is the maximum thrust certified for continuous use. This rating should be used, at the flight crew discretion, only when required to ensure safe flight (engine failure).

The FADEC commands the “Maximum Continuous” thrust rating:

- After a throttle reduction or a TOGA recovery
- For a thrust lever on the FLX/MCT detent.

MAXIMUM CLIMB

Applicable to: ALL

The “Maximum Climb” thrust rating is the maximum thrust approved for normal climb.
The FADEC commands this rating when the thrust lever is on the CL detent and no derated level entered in the MFD - PERF - CLB page.

POWER MANAGEMENT TABLE

Applicable to: ALL

DERATED CLIMB

Applicable to: ALL

The Derated Climb thrust rating is a reduced maximum thrust that the flight crew can select for the climb.
The FADEC manages the Derated Climb thrust rating when the thrust lever is set to the CL detent and a derated level is entered in the FMS - PERF - CLB page.

The Derated Climb thrust rating has the following economical advantages:
- Increased engine life
- Improved engine reliability
- Reduced direct maintenance costs.

There are three Derated Climb thrust ratings:
- Derated Climb 1 (DCL1)
- Derated Climb 2 (DCL2)
- Derated Climb 3 (DCL3).

The Derated Climb thrust rating progressively increases to the Maximum Climb (MCL) thrust rating (washout). The use of a Derated Climb thrust rating consequently does not affect the climb ceiling or the climb rate at the end of the climb.
The climb ratings, the associated thrust ratings and the indicative altitudes at which the washout begins (ISA conditions) are as follows.

CLB Thrust	Maximum Thrust Reduction from MCL Thrust	Progressive Washout to MCL Thrust from
MCL	0 %	N/A
DCL1	8 %	29 000 ft
DCL2	16 %	25 000 ft
DCL3	24 %	21 000 ft

The higher the temperature, the lower the washout altitude.
The economical advantages increase for high Derated Climb thrust ratings. The reduced direct maintenance costs usually compensate for the slight increase in the fuel consumed and the time necessary to climb.

The use of an appropriate Derated Climb thrust rating is recommended:
- When the aircraft is light, or
- In cool atmosphere, or
- When there are no obstacles or operational constraints to clear along the flight path.

DERATED CLIMB LEVEL DETERMINATION

Applicable to: ALL

GENERAL

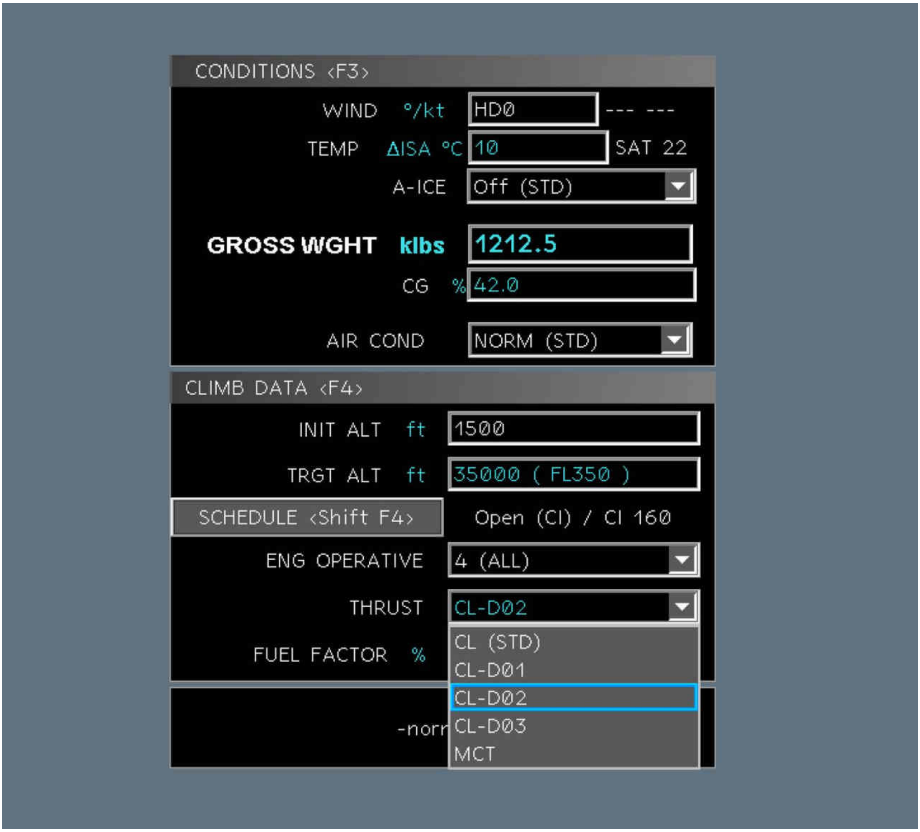
The flight crew selects the appropriate Derated Climb level before takeoff.
When possible, DCL3 is recommended. However, the operational constraints may require higher thrust levels, and it may not be possible to achieve these constraints with DCL3. In this case, the flight crew may select DCL2, DCL1, or even keep MCL.
Below is an example that illustrates a method to determine the appropriate Derated Climb level, when there is an altitude constraint at a specific ground distance from the runway (e.g. ATC requirement).
This method consists in successively checking if DCL3, DCL2, or DCL1, is appropriate for the clearance of the constraint. The MCL thrust rating should be used only when required.

EXAMPLE

The flight crew may use the IN-FLT PERF CLB module to determine the appropriate Derated Climb level.
For more information about the CLB module, *Refer to PER-IFT-CLB-CMI CLB Module Interface* .

ASSUMPTIONS

Assumptions



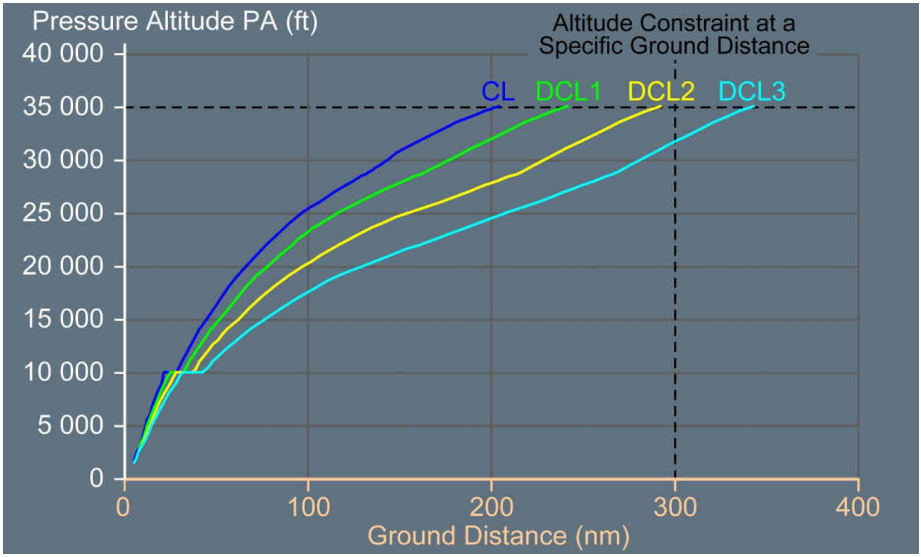
The example is based on the following assumptions:
- MTOW : 1 215 700 lb
- Airflow: NORM
- Anti-Ice: OFF

- Center of gravity: 42 %RC
- Climb speed profile: 250 kt up to an altitude of 10 000 ft - Open (CI) with CI = 210
- ISA conditions: ISA +10
- Altitude constraint: 35 000 ft at a ground distance of 300 nm from the runway
- Takeoff allowances from brake release to +1 500 ft :
  - Time: 3 min
  - Fuel: 3 200 lb
  - Distance: 5 nm .

  Note: *Consider these takeoff allowances as an example only.*

DERATED CLIMB LEVEL DETERMINATION

Derated Climb Level Determination



- IN-FLT PERF CLB computation with DCL3
  As illustrated above, the ground distance required to climb to 35 000 ft with DCL3 is more than the ground distance available to climb to the altitude constraint. This ground distance is the sum of the takeoff allowance distance plus the ground distance from 1 500 ft to 35 000 ft resulting from the IN-FLT PERF CLB computation with DCL3.
  The altitude constraint is not cleared. Therefore, the flight crew cannot select DCL3.
- IN-FLT PERF CLB computation with DCL2

As illustrated above, the ground distance required to climb to 35 000 ft with DCL2 is less than 250 nm . This ground distance is the sum of the takeoff allowance distance plus the ground distance from 1 500 ft to 35 000 ft resulting from the IN-FLT PERF CLB computation with DCL2.

The altitude constraint is cleared. Therefore, the flight crew can select DCL2.

L12

Note: *The flight crew can clear the DCL thrust rating at any time during the climb if required.*

To clear the DCL thrust rating, the flight crew can:

- *Select NONE in the DERATED CLB drop down list of the FMS - PERF - CLB page, or*
  For more information about the DERATED CLB drop down list of the FMS - PERF - CLB page, Refer to DSC-22-FMS-20-30-22FMS502BC PERF page .
- *Change the thrust lever position out of the CL detent and then set the thrust lever position back to the CL detent.*

MAXIMUM CRUISE

Applicable to: ALL

The “Maximum Cruise” thrust rating is the maximum thrust approved for normal cruise.
There is no thrust lever position corresponding to this thrust rating.
It is not displayed to the flight crew, and the THR limit which is displayed in cruise is the maximum climb THR (taking into account the air bleed effect).
The FG AFS uses the maximum cruise TPR to compute the aircraft maximum speed.

With A/THR disconnected, in cruise AEO , the flight crew should limit THR to the maximum cruise THR that is equal to the THR value displayed on the IN-FLT PERF application:

- For a CRZ calculation, and
- With CL (A/THR) as THRUST.

For more information about THR in the IN-FLT PERF application, *Refer to PER-IFT-CRZ-CRR-CRF THR* .

TAKEOFF PERFORMANCE OPTIMIZATION

Applicable to: ALL

GENERAL

Takeoff performance optimization is the process which aims at obtaining:
- The maximum performance limited takeoff weight (MTOW(perf))
- The maximum takeoff thrust reduction for the current weight.

Takeoff performance is optimized for each runway, the associated obstacles, flap setting and prevailing conditions (temperature, wind and QNH).

T.O PERF

The takeoff performance optimization process is made with the takeoff performance application (T.O PERF).

This application determines:
- MTOW(perf)
- The optimum thrust option.

T.O PERF provides the takeoff performance information to the flight crew that is necessary for an optimized takeoff.

The flight crew uses T.O PERF:
- During flight preparation: To determine the maximum takeoff weight limited by performance (e.g. runway, takeoff climb segments, obstacles)
- During OIS preparation, then before start clearance, and during taxi in the case of runway change: To obtain applicable takeoff data.

TAKEOFF PERFORMANCE PARAMETERS

Applicable to: ALL

The takeoff performance optimization process:
- Takes into account the parameters that affect takeoff performance
- Optimizes the parameters for which there is a possible range of values or settings.

The takeoff performance parameters are:
- The characteristics of the runway

L2
- Declared lengths (TORA , TODA , ASDA)
- Elevation
- Slope
- Obstacles.

For more information about the characteristics of the runway, *Refer to PER-TOF-TOC-RWY Airport Panel* .

L1 - The outside conditions

L2
- Temperature
- Wind
- QNH
- Anti-ice
- Runway state.

For more information about the outside conditions, *Refer to PER-TOF-TOC-OCD Outside Conditions Subpanel* .

L1 - The aircraft configuration

L2
- Aerodynamic configuration
- Air conditioning
- The derate level (in the case of a VMCG limitation).

For more information about the aircraft configuration, *Refer to Aircraft Configuration - Single Results* , or
For more information about the aircraft configuration, *Refer to Aircraft Configuration - Multiple Results* .

L1 - The aircraft status

L2
- MEL ,
- CDL .

For more information about the aircraft status, *Refer to PER-TOF-TOC-AFS AIRCRAFT STATUS Panel* .

L1 - The takeoff speeds.

L2
- V1
- V2.

L1 The following parameters can be optimized:
- Aerodynamic configuration
- Air conditioning
- Derate level (in the case of a VMCG limitation)
- Takeoff speeds.

SPEED OPTIMIZATION

Applicable to: ALL

Among the takeoff performance parameters that can be optimized, the takeoff speeds optimization has the largest potential for gain of takeoff weight.

The takeoff performance optimization process calculates the takeoff speeds (V1 and V2) that produce:

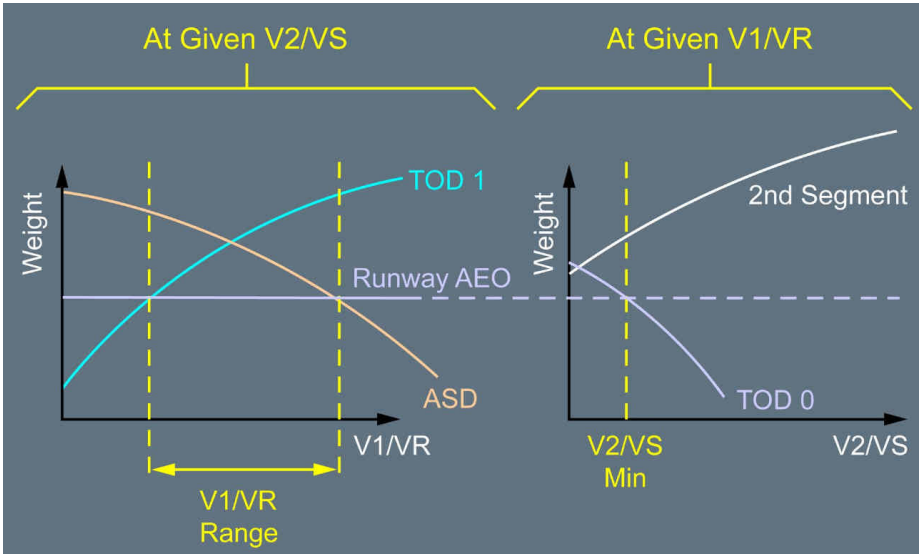
- MTOW(perf), or
- The maximum takeoff temperature for the current weight (in the case of a FLEX Takeoff).

This is done by calculating the performance limitations due to regulatory requirements versus speed.

L2 EXAMPLE

The graph below provides an example of a takeoff speed computation:

Weight vs. Speed



TOD 0	Takeoff Distance All Engines Operative (AEO)
TOD 1	Takeoff Distance One Engine Inoperative (OEI)

The takeoff performance of a four-engine aircraft usually results from the all-engine runway limitation (Runway AEO). In this example, Runway AEO corresponds to TOD 0.
The graph on the right indicates that the optimum V2/VS is the minimum value of the V2/VS range.

Due to the Runway AEO limitation, the takeoff weight that can be achieved is the same for a range of V1/VR:

- At the minimum of the V1/VR range (V1 min), the takeoff weight is limited by both the Takeoff Distance (TOD) and the Runway AEO
- Along the V1/VR range, the takeoff weight is only limited by the Runway AEO
- At the maximum of V1/VR range (V1 max), the takeoff weight is limited by both the Accelerate-Stop Distance (ASD) and the Runway AEO.

In addition, optimum V1 may be affected by the obstacles.

Intentionally left blank

T.O PERF INITIALIZATION

Applicable to: ALL

FLT OPS STS

The Flight Operations Status (FLT OPS STS) page defines the aircraft context (aircraft registration, MSN) and the flight context (flight number, city pair).

The aircraft and flight contexts aim at:
- Securing the communication between the FLT OPS applications
- Preventing the use of incorrect inputs coming from another flight.

This common reference page enables the other FLT OPS applications to synchronize with the aircraft and flight data entered in the FLT OPS STS page.
For more information about the FLT OPS STS page, *Refer to DSC-46-20-10-30 FLT OPS STS Page* .

PREREQUISITE TO START T.O PERF

FLIGHT OPERATION STATUS

To enable the launch of T.O PERF, the following mandatory parameters must be filled in the FLT OPS STS page:
- The aircraft registration (ACFT REGISTRATION)
- The manufacturer serial number (MSN)
- The flight number (FLT NBR)
- The departure airport (FROM).

If one of the previous parameters is not defined, T.O PERF cannot be launched.

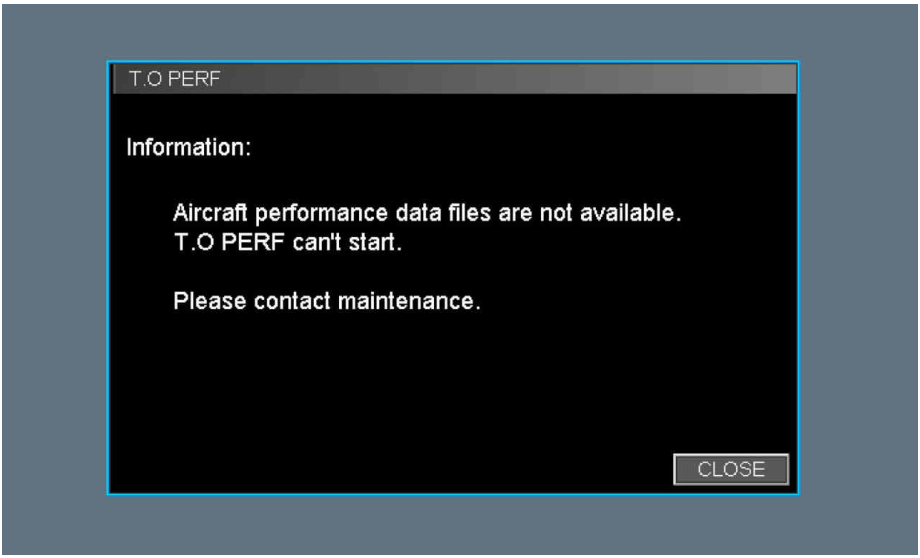
Note: If no destination airport (TO) is defined in the FLT OPS STS page, T.O PERF can still be launched.

When the flight crew launches T.O PERF, the departure airport (FROM) of the FLT OPS STS page is retrieved in T.O PERF and displayed in yellow in the AIRPORT field of the SINGLE RWY COMPUTATION panel.

PERFORMANCE DATABASES

When the flight crew starts T.O PERF without the relevant performance databases, the following error message appears and T.O PERF cannot start:

Error at T.O PERF Start



The flight crew needs to contact the ground.

CHANGE OF AIRPORT IN T.O PERF

Applicable to: ALL

When the flight crew directly changes the departure airport in T.O PERF, this is considered as a next flight simulation.
As a consequence, the FLT OPS STS page parameters do not change.

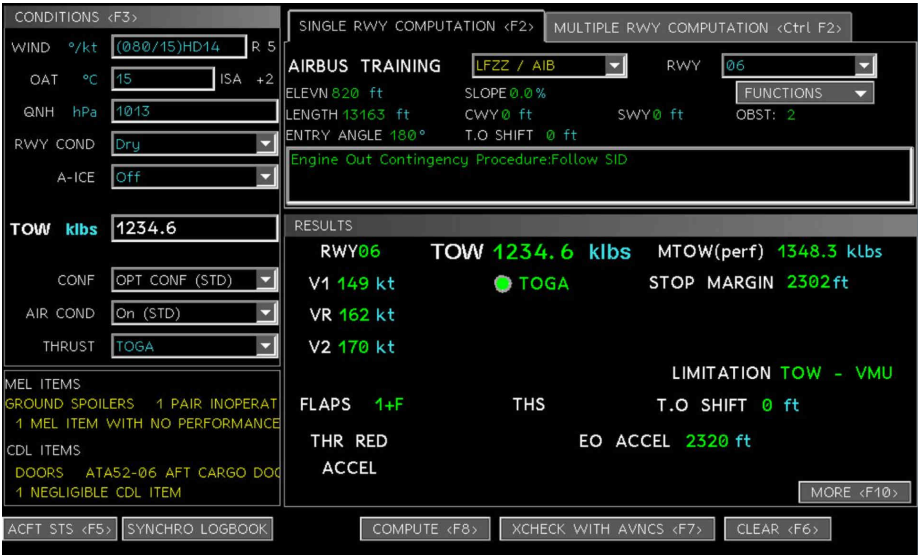
T.O PERF becomes in standalone mode (it is not anymore in the same context as other applications):

- All input data of T.O PERF are reset to default values
- TOW is defaulted to MSTOW
- Previous T.O PERF results are deleted
- MEL / CDL items still remain
- Data from LOADSHEET and OPS LIBRARY are not available anymore (communication capability with LOADSHEET or OPS LIBRARY is lost).

T.O PERF INTERFACE

Applicable to: ALL

T.O PERF Interface



SINGLE RWY COMPUTATION / MULTIPLE RWY COMPUTATION

The flight crew can:
- Select one, or more, runway(s)
- View the runway characteristics
- Modify the selected runway(s).

For more information about airports and runways, *Refer to PER-TOF-TOC-RWY Airport Panel* .

CONDITIONS

This panel displays the current outside conditions and the aircraft configuration:

OUTSIDE CONDITIONS

The flight crew enters the outside conditions.
For more information about the outside conditions, *Refer to PER-TOF-TOC-OCD Outside Conditions Subpanel* .

AIRCRAFT CONFIGURATION

The flight crew selects the aircraft configuration.

For more information about the aircraft configuration:
- *Refer to Aircraft Configuration - Single Results* , or
- *Refer to Aircraft Configuration - Multiple Results* .

AIRCRAFT STATUS

The flight crew can select:
- Inoperative systems impacting takeoff performance
- CDL items impacting takeoff performance.

For more information about the aircraft status, *Refer to PER-TOF-TOC-AFS AIRCRAFT STATUS Panel* .

SYNCHRO LOGBOOK

The flight crew can recover the eLogbook status by clicking on the "SYNCHRO LOGBOOK" button.
For more information about the SYNCHRO LOGBOOK function, *Refer to PER-TOF-TOC-AFS Synchronization with Logbook* .

RESULTS

The layout of the RESULTS panel may be different, depending on the Operator policy.

For more information about the optimization results:
- *Refer to Single Results - Single Runway Computation* , or
- *Refer to Single Results - Multiple Runway Computation* , or
- *Refer to Multiple Results - Single Runway Computation* , or
- *Refer to Multiple Results - Multiple Runway Computation - One Step* , or
- *Refer to Multiple Results - Multiple Runway Computation - Two Steps* .

XCHECK WITH AVNCS

The flight crew can crosscheck the FMS takeoff performance entries with the OIS takeoff performance results.

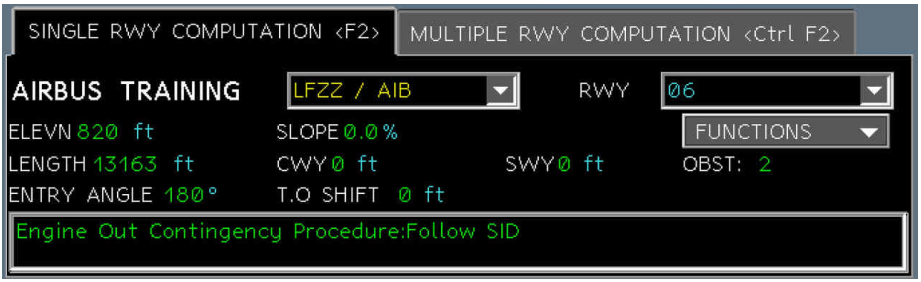
For more information about the XCHECK WITH AVNCS function:
- *Refer to XCHECK WITH AVNCS - Single Results* , or
- *Refer to XCHECK WITH AVNCS - Multiple Results* .

AIRPORT PANEL

Applicable to: ALL

The flight crew uses the airport panel to select the airport and runway(s).

Airport Panel



SINGLE RWY COMPUTATION

For more information about the SINGLE RWY COMPUTATION panel:

- *Refer to SINGLE RWY COMPUTATION Panel - Length-Clearway-Stopway* , or
- *Refer to SINGLE RWY COMPUTATION Panel - TORA-TODA-ASDA* .

MULTIPLE RWY COMPUTATION

For more information about the MULTIPLE RWY COMPUTATION panel:

- *Refer to MULTIPLE RWY COMPUTATION Panel - Length-Clearway-Stopway* , or
- *Refer to MULTIPLE RWY COMPUTATION Panel - TORA-TODA-ASDA* .

FUNCTIONS

For more information about the runway modification FUNCTIONS:

- *Refer to FUNCTIONS - Reduced Mode* .

SINGLE RWY COMPUTATION PANEL - LENGTH-CWY-SWY

Applicable to: ALL

GENERAL

A takeoff performance calculation takes into account the following runway characteristics:

- Declared lengths

L2 For more information about declared lengths, *Refer to PER-TOF-TOC-RWY-DEL Declared Lengths* .

L1 - Elevation

L2 For more information about elevation, *Refer to PER-TOF-TOC-RWY Elevation* .

L1 - Slope

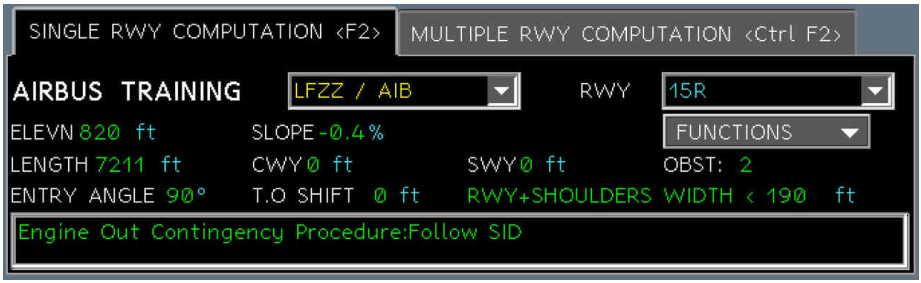
L2 For more information about slope, *Refer to PER-TOF-TOC-RWY Slope* .

L1 - Obstacles.

L2 For more information about obstacles, *Refer to PER-TOF-TOC-RWY Obstacles* .

L1 **T.O PERF**

SINGLE RWY COMPUTATION Panel



The flight crew uses the SINGLE RWY COMPUTATION panel to select the runway.

AIRPORT SELECTION

The AIRPORT drop-down list provides a list of available airports. This list is sorted by airport codes.

RUNWAY SELECTION

When the flight crew has selected an airport, the RWY drop-down list provides a choice of runways applicable to that airport.

RUNWAY CHARACTERISTICS

Runway characteristics are:

- Runway ID

- Elevation
- Slope
- Length
- Length of clearway (CWY)
- Length of stopway (SWY)
- Number of obstacles

L2 For more information about obstacles, *Refer to VIEW OBST - Reduced Mode* .

L1 - Runway entry angle:

L2
- 0 ° for a straight entry, or
- 90 ° for a 90 ° taxiway entry to the runway, or
- 180 ° for a turnaround on the runway.

L1 - Takeoff shift

L2 For more information about takeoff shift, *Refer to MODIFY RWY - Reduced Mode* .

L1 - Runway plus shoulders width less than 58 m (if applicable)
For more information about runway plus shoulders width, *Refer to PER-TOF-TOC-RWY Operations on Runway + Shoulders less than 58 m Wide* .

- Runway comment (if applicable).
The runway comment panel usually displays the takeoff procedure.

L2 For more information about the runway comment, *Refer to PER-TOF-TOC-RWY Runway Comment* .

SINGLE RWY COMPUTATION PANEL - TORA-TODA-ASDA

Applicable to: ALL

GENERAL

A takeoff performance calculation takes into account the following runway characteristics:

- Declared lengths

L2 For more information about declared lengths, *Refer to PER-TOF-TOC-RWY-DEL Declared Lengths* .

L1 - Elevation

L2 For more information about elevation, *Refer to PER-TOF-TOC-RWY Elevation* .

L1 - Slope

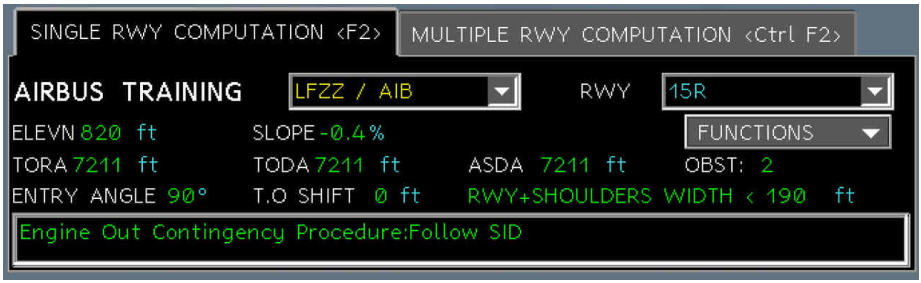
L2 For more information about slope, *Refer to PER-TOF-TOC-RWY Slope* .

L1 - Obstacles.

L2 For more information about obstacles, *Refer to PER-TOF-TOC-RWY Obstacles* .

L1 **T.O PERF**

SINGLE RWY COMPUTATION Panel



The flight crew uses the SINGLE RWY COMPUTATION panel to select the runway.

AIRPORT SELECTION

The AIRPORT drop-down list provides a list of available airports. This list is sorted by airport codes.

RUNWAY SELECTION

When the flight crew has selected an airport, the RWY drop-down list provides a choice of runways applicable to that airport.

RUNWAY CHARACTERISTICS

Runway characteristics are:

- Runway ID

- Elevation
- Slope
- Takeoff Run Available (TORA)
- Takeoff Distance Available (TODA)
- Accelerate-Stop Distance Available (ASDA)
- Number of obstacles

L2 For more information about obstacles, *Refer to VIEW OBST - Reduced Mode* .

L1 - Runway entry angle:

L2
- 0 ° for a straight entry, or
- 90 ° for a 90 ° taxiway entry to the runway, or
- 180 ° for a turnaround on the runway.

L1 - Takeoff shift

L2 For more information about takeoff shift, *Refer to MODIFY RWY - Reduced Mode* .

L1 - Runway plus shoulders width less than 58 m (if applicable)
For more information about runway plus shoulders width, *Refer to PER-TOF-TOC-RWY Operations on Runway + Shoulders less than 58 m Wide* .

- Runway comment (if applicable).
The runway comment panel usually displays the takeoff procedure.

L2 For more information about the runway comment, *Refer to PER-TOF-TOC-RWY Runway Comment* .

DECLARED LENGTHS

Applicable to: ALL

TAKEOFF RUN AVAILABLE (TORA)

The Takeoff Run Available (TORA) is either:
- The length of runway declared available and suitable by the appropriate Authority, or
- The distance from an intermediate taxi crossing intersection to the end of the runway.

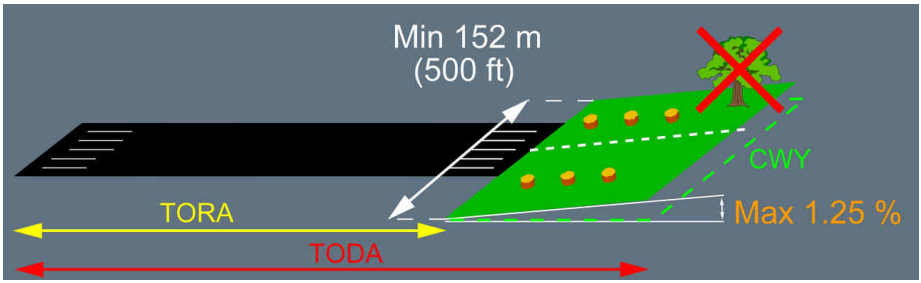
TAKEOFF DISTANCE AVAILABLE (TODA)

The Takeoff Distance Available (TODA) is equal to the length of TORA, plus the length of any associated clearway (CWY).

L2 A clearway is an area that is beyond the end of TORA, and:
- Uses the same extended centerline as the runway
- Does not exceed an upward slope of 1.25 %
- Is at least 500 ft wide
- Does not have any protruding terrain or obstacles, except threshold lights (if their height above the surface is less than 2.16 ft).

A clearway need not have bearing strength and may be land or water.

Clearway



L1 ACCELERATE-STOP DISTANCE AVAILABLE (ASDA)

The Accelerate-Stop Distance Available (ASDA) is equal to the length of TORA, plus the length of any associated stopway (SWY).

L2 A stopway is an area that is beyond the end of TORA, and is:
- At least as wide as the runway, and has the same extended centerline
- Able to support the aircraft during an aborted takeoff
- Designated by airport authorities for decelerating an aircraft, in the case of an aborted takeoff.

LINEUP DISTANCES

For takeoff performance computations, TODA and ASDA must be reduced by the lineup distance corrections, in the case of:

- A 90 ° taxiway entry to the runway

90 Degree Runway Entry			
NLG steering angle	Maximum effective steering angle	Minimum lineup distance correction	
		TODA	ASDA
70 °	69.5 °	74.6 ft	172.5 ft

- A 180 ° turnaround on the runway.

180 Degree Turnaround				
Minimum lineup distance correction		Required minimum runway width	Nominal lineup distance on a 200 ft runway width	
TODA	ASDA		TODA	ASDA
121.9 ft	219.8 ft	222 ft	162.8 ft	260.6 ft

ELEVATION

Applicable to: ALL

Airport elevation has an impact on pressure altitude.

For more information about the effect of pressure altitude on takeoff performance, *Refer to PER-TOF-TOC-OCD QNH* .

SLOPE

Applicable to: ALL

Takeoff is authorized on runways that have an average slope between -2 % and +2 % .

L2 Upward slopes have dual effects on performance:

- Acceleration distances increase, but
- Deceleration distances decrease.

As a result, it is not possible to make a general statement on the overall effect of runway slopes on MTOW(perf).

OBSTACLES

Applicable to: ALL

Obstacles along the takeoff flight path within a departure sector must be cleared by the intended takeoff flight path with a regulatory margin.

L2 A departure sector, also called takeoff funnel, represents an area surrounding the takeoff flight path, within which all obstacles must be cleared, assuming they are all projected on the intended track.

OPERATIONS ON RUNWAY + SHOULDERS LESS THAN 190 FT WIDE

Applicable to: ALL

GENERAL

A specific takeoff procedure has to be applied when the sum of the runway width plus hard shoulders is less than 190 ft . This specific takeoff procedure induces a penalty on the takeoff performance.

For more information about this specific takeoff procedure, *Refer to Operations on Runway + Shoulders less than 190 ft Wide* .

T.O PERF

When the Airport panel displays the following message: "RWY+SHOULDERS WIDTH < 190 ft", T.O PERF automatically takes into account the takeoff performance penalty induced by the specific takeoff procedure "Operations on Runway + Shoulders less than 190 ft Wide".

L2 The progressive thrust setting has an impact on takeoff performance.

L1 *Note:* *The message "RWY+SHOULDERS WIDTH < 190 ft" displayed on the Airport panel is not sufficient to directly apply the specific takeoff procedure. The flight crew must check with the Airport Authorities whether the runway plus shoulder width is really less than 190 ft or not.*

L2 If there is no value in the field "Shoulder" in the airport data, the message "RWY+SHOULDERS WIDTH < 190 ft" may be displayed in the Airport panel because T.O PERF assumes that no value in the field "Shoulder" means that the shoulder width is equal to 0.

RUNWAY COMMENT

Applicable to: ALL

The runway comment panel displays additional data on the selected runway as per Operator policy. The runway comment panel usually displays the engine out contingency takeoff procedure.

CREATE RWY - REDUCED MODE

Applicable to: ALL

FUNCTIONS

The FUNCTIONS drop down list enables the flight crew to:

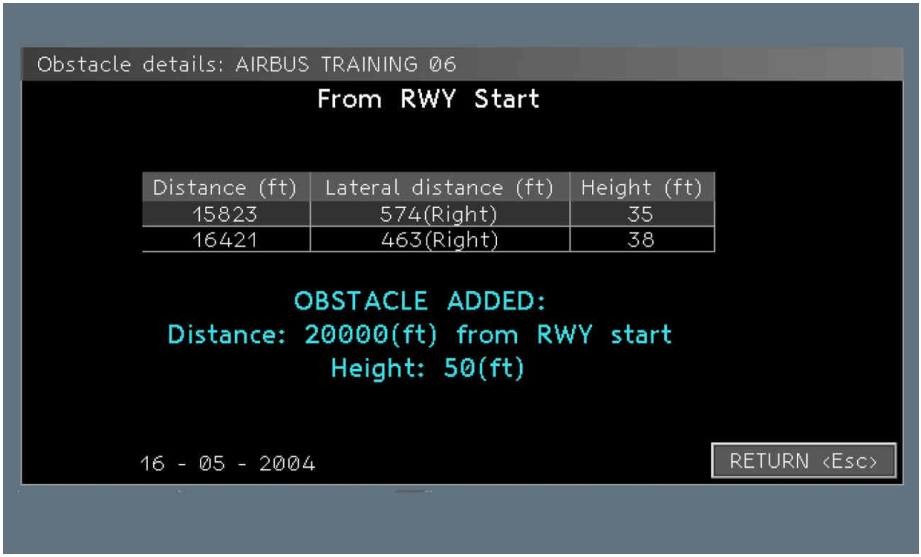
- VIEW OBST: To display information about the obstacles associated to the selected runway
- MODIFY RWY: To modify an existing runway.

VIEW OBST

The flight crew uses the VIEW OBST subpanel to display information about the obstacles associated to the selected runway.

L2 The flight crew can access this subpanel by selecting VIEW OBST in the FUNCTIONS drop down list of the SINGLE RWY COMPUTATION panel.

Obstacle Details Subpanel



L1 **HEADER**

The header identifies the selected runway.

OBSTACLE DETAILS

The VIEW OBST subpanel contains information about the obstacle(s) applicable to the selected runway.

The following data is displayed:
- Distance from the runway entry point (start of runway area or intermediate taxi crossing intersection)
- Obstacle lateral distance from the runway centerline
- Obstacle height.

The date associated to the obstacles information appears at the bottom of the Obstacle details panel.

ADDITIONAL OBSTACLE

When the flight crew adds an obstacle via the ADD 1 OBSTACLE function, the obstacle appears at the bottom of the panel.

L2 The flight crew can access this function by selecting MODIFY RWY in the FUNCTIONS drop down list of the SINGLE RWY COMPUTATION panel.
For more information about the ADD 1 OBSTACLE function, *Refer to PER-TOF-TOC-RWY-CRR MODIFY RWY* .

MODIFY RWY

The flight crew uses the MODIFY RWY subpanel to modify the characteristics of the selected runway by either decreasing the runway length, or by adding an obstacle.

L2 The flight crew can access this subpanel by selecting MODIFY RWY in the FUNCTIONS drop down list of the SINGLE RWY COMPUTATION panel.

MODIFY RWY Subpanel

L1 RUNWAY LENGTH REDUCTION

The flight crew can enter the runway length reduction from either end.

The runway length (LENGTH) displayed on the SINGLE RWY COMPUTATION panel is reduced according to the entered value.

The Takeoff Shift (T.O SHIFT) displayed on the SINGLE RWY COMPUTATION panel is increased according to the entered value, if the runway length has been decreased from the runway entry point (RWY START).

L2 The takeoff shift is a reduction of the takeoff distances (TORA , TODA , ASDA) due to a shifted entry of the aircraft on the runway.

L1 The SINGLE RWY COMPUTATION panel displays the label “length modified” to indicate that the flight crew has modified the runway length.

If the flight crew reduces the runway length from the RWY end, the length of the CWY and SWY are automatically set to 0.

ADD 1 OBSTACLE

One more obstacle can be added for the selected runway.
The flight crew can enter the obstacle longitudinal distance from either end.
Then, the flight crew enters the obstacle height.
The SINGLE RWY COMPUTATION panel displays the label “OBSTACLE ADDED” to indicate that the flight crew has added an obstacle.
This added obstacle is displayed on the VIEW OBST subpanel.

L2 For more information about the VIEW OBST subpanel, *Refer to PER-TOF-TOC-RWY-CRR VIEW OBST* .

L1 RWY+SHOULDERS WIDTH < 190 FT

The flight crew can activate or deactivate the option "RWY+SHOULDERS WIDTH < 190 ft".

L2 For more information about this option, *Refer to PER-TOF-TOC-RWY Operations on Runway + Shoulders less than 58 m Wide* .

L1 ENTRY ANGLE

The flight crew can modify the runway entry angle via the Entry Angle drop-down list.
The runway entry angle (ENTRY ANGLE) displayed on the SINGLE RWY COMPUTATION panel is updated according to the selected value.
The SINGLE RWY COMPUTATION panel displays the label “ENTRY ANGLE MODIFIED” to indicate that the flight crew has modified the runway entry angle.

MULTIPLE RWY COMPUTATION PANEL - LENGTH-CWY-SWY

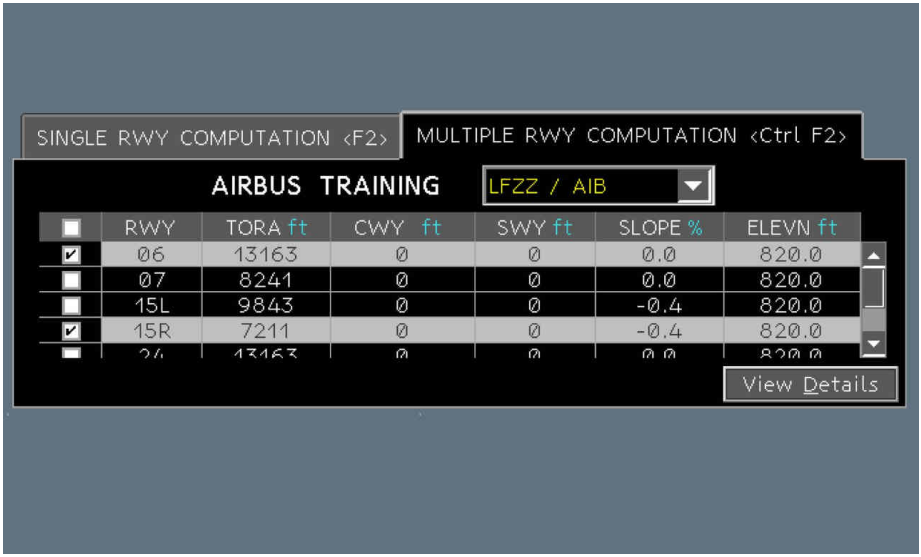
Applicable to: ALL

The flight crew uses the MULTIPLE RWY COMPUTATION panel to select several runways for which optimization will be performed in the current conditions.

The flight crew may use this feature during OIS preparation to anticipate a possible runway change.

L2 This function increases calculation time.

MULTIPLE RWY COMPUTATION Panel



L1 *Note: The label "TORA" is displayed instead of the label "LENGTH" on the MULTIPLE RWY COMPUTATION panel.*

AIRPORT SELECTION

The AIRPORT drop-down list provides a list of the available airports.

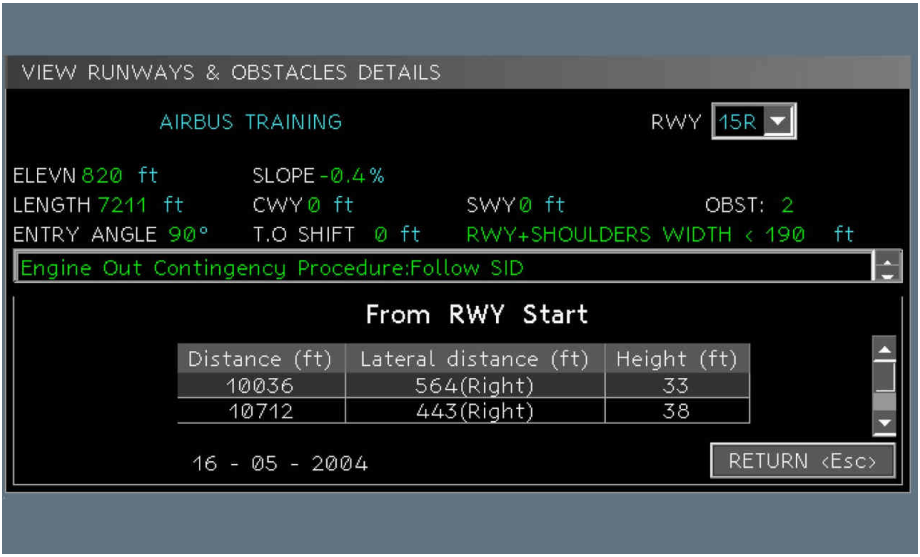
RUNWAY TABLE

The flight crew uses the runway table to select the runways on which the computation will be performed.

VIEW DETAILS

When the flight crew selects one or multiple runways in the table, the flight crew can click on the View Details button to open the VIEW RUNWAYS & OBSTACLES DETAILS panel. This panel displays information associated to the selected runway(s).
The flight crew then uses the RWY drop down list to access the information for each selected runway.

VIEW RUNWAYS & OBSTACLES DETAILS Panel



MULTIPLE RWY COMPUTATION PANEL - TORA-TODA-ASDA

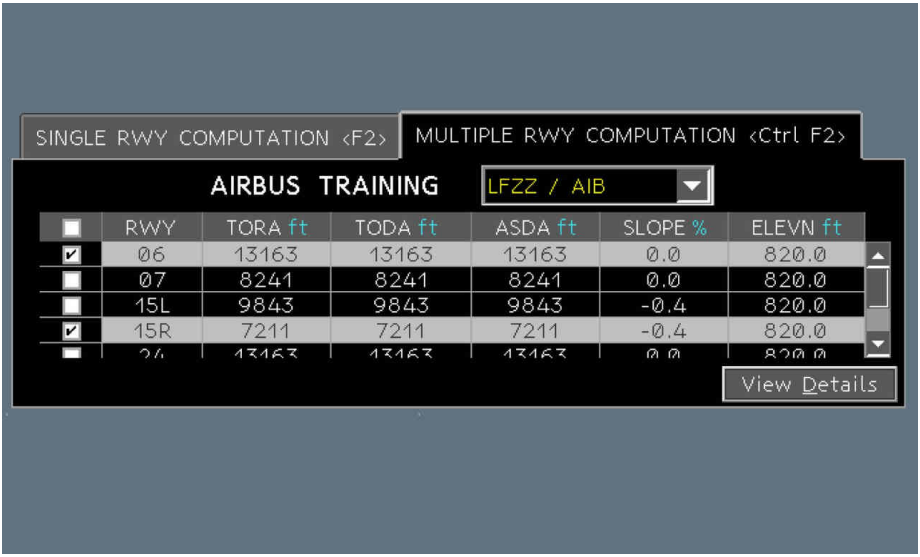
Applicable to: ALL

The flight crew uses the MULTIPLE RWY COMPUTATION panel to select several runways for which optimization will be performed in the current conditions.

The flight crew may use this feature during OIS preparation to anticipate a possible runway change.

L2 This function increases calculation time.

MULTIPLE RWY COMPUTATION Panel



L1 AIRPORT SELECTION

The AIRPORT drop-down list provides a list of the available airports.

RUNWAY TABLE

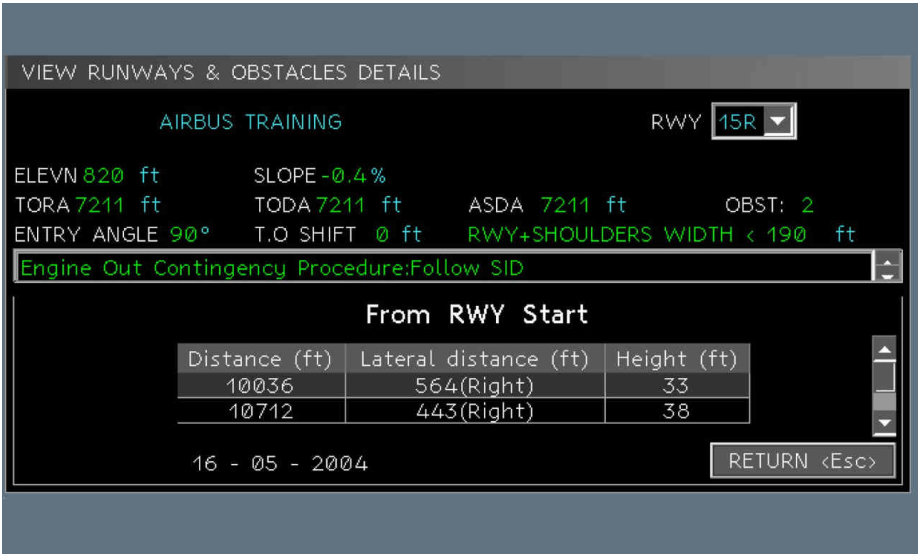
The flight crew uses the runway table to select the runways on which the computation will be performed.

VIEW DETAILS

When the flight crew selects one or multiple runways in the table, the flight crew can click on the View Details button to open the VIEW RUNWAYS & OBSTACLES DETAILS panel. This panel displays information associated to the selected runway(s).

The flight crew then uses the RWY drop down list to access the information for each selected runway.

VIEW RUNWAYS & OBSTACLES DETAILS Panel



Intentionally left blank

OUTSIDE CONDITIONS SUBPANEL

Applicable to: ALL

The Outside Conditions subpanel provides the following information:

- Wind
- Temperature (OAT)
- QNH
- Runway conditions
- Anti-ice.

Outside Conditions Subpanel

WIND

Applicable to: ALL

GENERAL

L2 The longitudinal wind component affects the aircraft ground speed, and therefore the ground distance necessary to accelerate to liftoff speed (VLOF).

L1 The takeoff distance decreases in the case of headwind, and increases in the case of tailwind.

L2 As per regulation, the computation is based on 150 % of the entered tailwind, and 50 % of the entered headwind.

L1 The crosswind component does not affect the calculation of the takeoff distance. However, a maximum crosswind component is demonstrated.
For more information about crosswind limitation, *Refer to PER-TOF-CTA-CWD Crosswind* .
In addition, the flight crew must apply a specific thrust application procedure in the case of a crosswind above 23 kt and/or tailwind. This specific thrust application procedure increases the takeoff distance.
For more information about the specific thrust application procedure, *Refer to Standard Operating Procedures - Takeoff Thrust Setting* .

T.O PERF

There are two ways to define wind values:
- Longitudinal Speed Component
- Direction/Speed (or Direction/Speed/Gust) Combination.

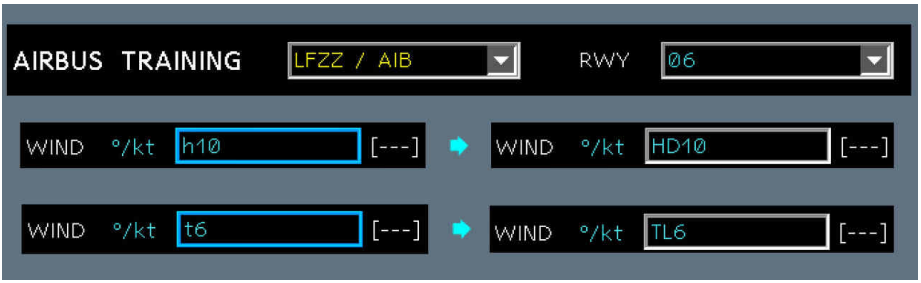
The Direction/Speed (or Direction/Speed/Gust) Combination is required in the case of a MULTIPLE RUNWAY COMPUTATION.

Note: *Displayed wind values are rounded mathematically instead of conservatively, but there is no impact on the computation, which uses exact values.*

LONGITUDINAL SPEED COMPONENT

The flight crew enters the longitudinal component with:
- H or HD followed by the headwind speed (e.g. H10 or HD5), or
- T or TL followed by the tailwind speed (e.g. T6 or TL8).

Wind Values Input - Longitudinal Speed Component



DIRECTION/SPEED (OR DIRECTION/SPEED/GUST) COMBINATION

This wind input mode is compulsory when computations are made on multiple runways.

The flight crew can enter:
- The wind direction and the wind speed, or
- The wind direction, the wind speed, and the gust, if this option is enabled.

Direction/Speed Combination

The speed entry is projected along the runway axis and perpendicular to the runway axis. The longitudinal projection follows the same display rules as the longitudinal speed component entry mode.

T.O PERF displays the crosswind as:
- R, if the wind comes from the right, or
- L, if the wind comes from the left.

Wind Values Input - Direction/Speed Combination

Direction/Speed/Gust Combination

This entry mode is possible if a maximum crosswind limit is defined as gust included for one RWY COND at least.

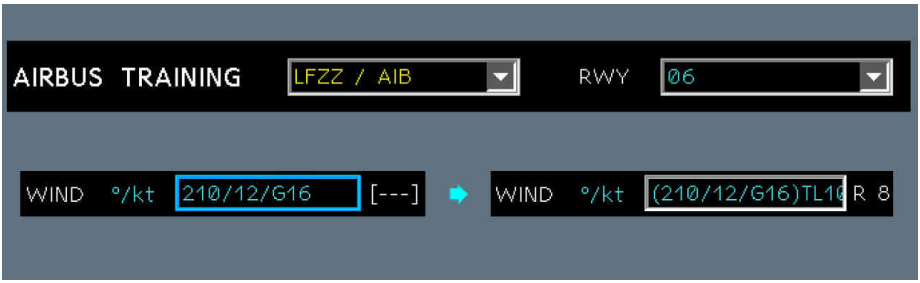
In this case, the flight crew can enter the value of the gust with the prefix G followed by the gust value (e.g. G16).
The speed entry (gust respectively) is projected along the runway axis and perpendicular to the runway axis.
The longitudinal projection follows the same display rules as the longitudinal speed component entry mode.

T.O PERF displays the crosswind as:
- R, if the wind comes from the right, or
- L, if the wind comes from the left.

If the flight crew enters the gust, T.O PERF displays the perpendicular projection of the gust as the crosswind.

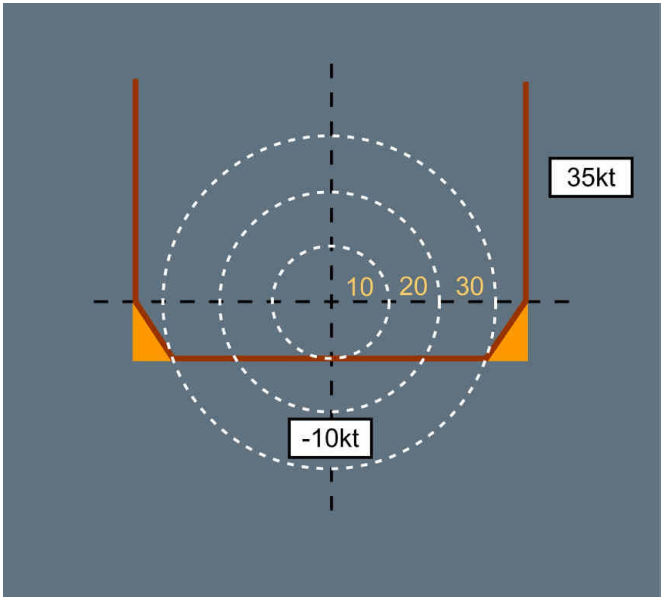
T.O PERF uses:
- The gust perpendicular component for the check of the maximum crosswind limitation if this one is defined as gust included for the selected RWY COND
- The steady wind perpendicular component for the check of the maximum crosswind limitation if this one is not defined as gust included for the selected RWY COND.

Wind Values Input - Direction/Speed/Gust Combination



COMBINATION OF CROSSWIND AND TAILWIND

Crosswind / Tailwind Envelope



When the flight crew enters a specific combination of crosswind and tailwind included in the orange area of the illustration above, T.O PERF displays the following error message: "Risk of engine pumping with this combination of Crosswind and Tailwind. Takeoff not allowed on QFU: ***".

Engine pumping means engine stall.

The flight crew cannot run the computation.

OUTSIDE AIR TEMPERATURE

Applicable to: ALL

GENERAL

Temperature has an effect on speed and on thrust.

TEMPERATURE EFFECT ON SPEED

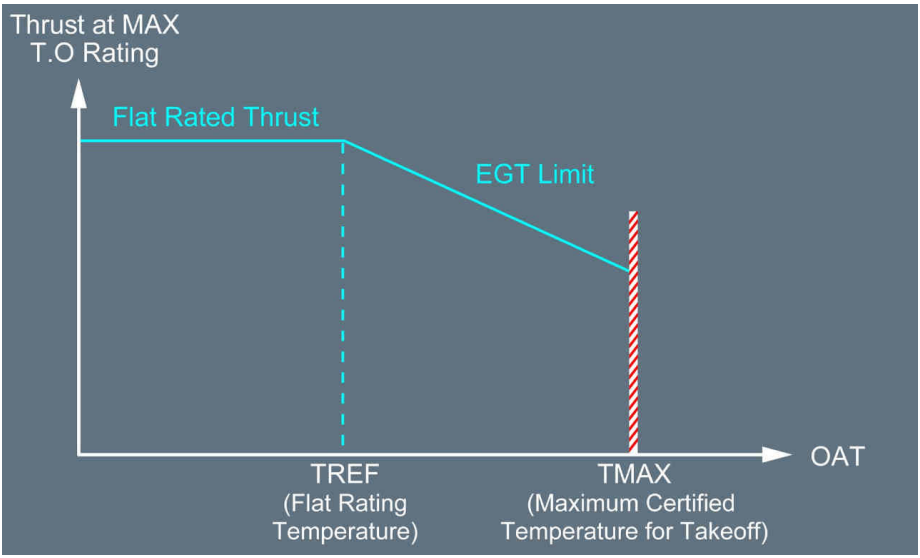
L2 When the Outside Air Temperature (OAT) increases, the air density ρ decreases.

L1 When the OAT increases, a higher true airspeed is required in order to maintain the same lift.
At high temperatures, the takeoff distances are longer.

TEMPERATURE EFFECT ON THRUST

L2 At specific altitudes, takeoff thrust will vary as follows, depending on the OAT :

Thrust vs. Temperature



The thrust provided by the engines at takeoff rating (TOGA) versus OAT is constant up to the Flat Rating Temperature (TREF).
When OAT goes above the TREF , available thrust decreases to avoid exceeding the Exhaust Gas Temperature (EGT), until the OAT reaches the Maximum Certified Temperature For Takeoff (TMAX).

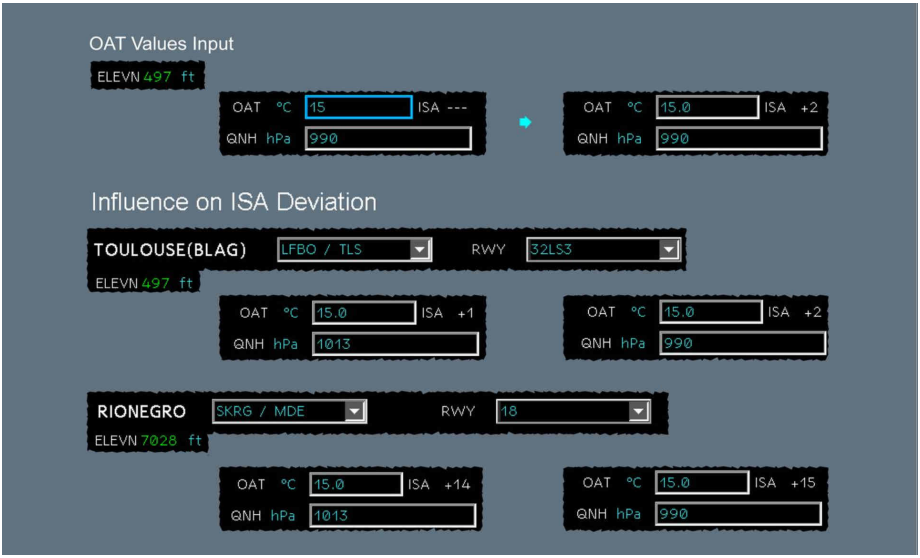
L1 Thrust varies depending on the OAT .

Therefore, at high temperatures, the takeoff distance increases and the takeoff climb gradient decreases.

L2 The Power Management tables provide the value of the thrust parameter, depending on the OAT and altitude.

L1 **T.O PERF**

OAT Input



OAT VALUE INPUT

Any deviation from the International Standard Atmosphere (ISA) is automatically computed and displayed next to the OAT field.

INFLUENCES ON ISA DEVIATION

The deviation from ISA is influenced by:
- The airport elevation
- The QNH value.

L2 For more information about the QNH , *Refer to PER-TOF-TOC-OCD QNH* .

QNH

Applicable to: ALL

GENERAL

The QNH is the pressure at the Mean Sea Level (MSL).

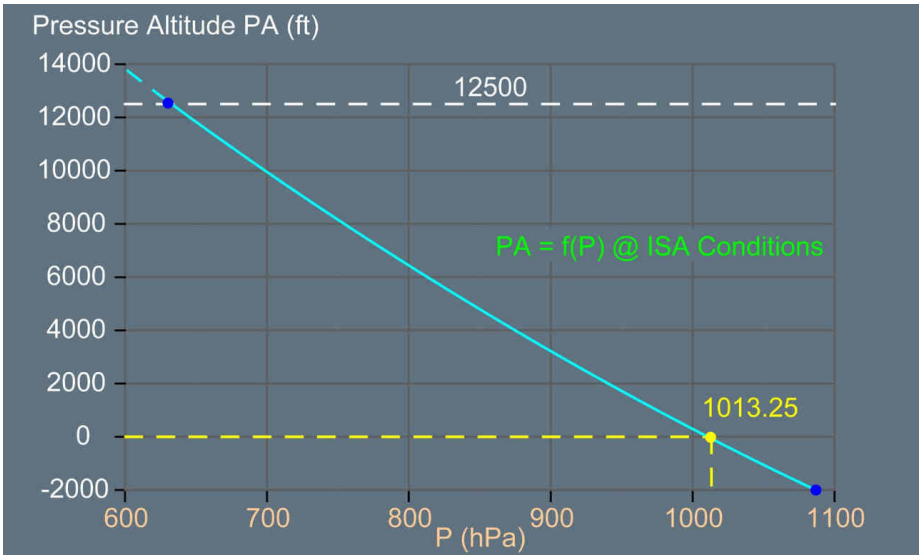
L2 The QNH is calculated from:
- The airport atmospheric pressure
- The airport elevation
  The airport elevation is the geometric altitude of the airport.
- The standard pressure law from ISA atmosphere.

At the airport level, with the QNH setting, in ISA conditions, the altimeter indicates the airport elevation.

L1 The airport Pressure Altitude (PA) depends on the QNH and the airport elevation.

L2 The PA is a barometric measurement converted into an altitude via the ISA law.

PA Function of Pressure (P)



L1 The QNH affects the aircraft takeoff speed and engine thrust.

QNH EFFECT ON TAKEOFF SPEED

When the QNH decreases at a given airport elevation:
- The PA increases
- The air density ρ decreases
- A higher TAS is required for takeoff in order to maintain the same lift
- The takeoff distance is longer.

QNH EFFECT ON ENGINE THRUST

When the QNH decreases at a given airport elevation:
- The PA increases
- The available engine thrust decreases
- The takeoff distance increases
- The takeoff climb gradients decrease.

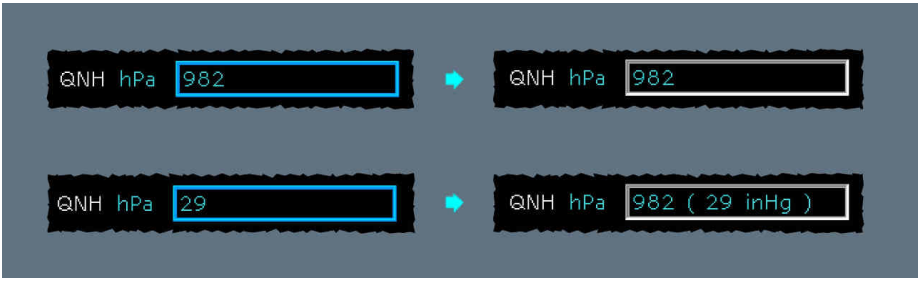
T.O PERF

The QNH is the input parameter that determines the pressure altitude, taking into account the airport elevation.

The flight crew can enter a QNH using the following units:
- Hecto Pascal (hPa)
- Inch of Mercury (inHg).

T.O PERF automatically detects the QNH format. For example, when the flight crew enters 29 for the QNH, T.O PERF automatically converts the value into the appropriate one for hPa unit.

QNH Input



L2 The airport elevation affects the QNH range.

RUNWAY CONDITIONS

Applicable to: ALL

GENERAL

The runway surface condition affects the takeoff performance and must be taken into account for MTOW(PERF) calculation.
For more information about the runway conditions, *Refer to Runway Contamination* .

T.O PERF

The flight crew selects one of the following settings from the RWY COND drop-down list depending on the runway surface condition.

DRY

The flight crew selects “Dry” for dry and damp runways.

WET

The flight crew selects “Wet” for runways covered with:
- Less than 0.12 in of Water, or
- Equivalent contaminants in terms of performance:
  - Less than 0.12 in of Slush, or
  - Less than 0.16 in of Wet Snow, or
  - Less than 0.59 in of Dry Snow.

For more information about equivalences, *Refer to PER-TOF-CTA Equivalences for Performance* .

WATER 1/4" (6.3 MM)

The flight crew selects ”Water 1/4” (6.3 mm)” between 0.12 in and 0.25 in of Standing Water.

WATER 1/2" (12.7 MM)

The flight crew selects ”Water 1/2” (12.7 mm)” between 0.25 in and 0.50 in of Standing Water.

L2 For takeoff performance assessment, in the case of Fluid Contaminant (Water, Slush), the contaminant depth has a dual effect on performance. The contaminant drag has a negative effect on the acceleration part, but a favorable effect on the deceleration segment. So, the takeoff performance for the higher contaminant depth is not systematically conservative versus the lower depth one.
When the flight crew performs a takeoff performance computation with a runway condition of ”Water 1/2” (12.7 mm)”, T.O PERF automatically performs a second computation with a runway condition of ”Water 1/4” (6.3 mm)” and chooses the more penalizing results (lower MTOW(PERF)).

L1 **SLUSH 1/4" (6.3 MM)**

The flight crew selects “Slush 1/4" (6.3 mm)” for runways covered with:
- Between 0.12 in and 0.25 in of Slush, or
- Equivalent contaminants in terms of performance:
  - Between 0.16 in and 0.50 in of Wet Snow, or
  - Between 0.59 in and 2.00 in of Dry Snow.

For more information about equivalences, *Refer to PER-TOF-CTA Equivalences for Performance* .

SLUSH 1/2" (12.7 MM)

The flight crew selects “Slush 1/2" (12.7 mm)” for runways covered with:
- Between 0.25 in and 0.50 in of Slush, or
- Equivalent contaminants in terms of performance:
  - Between 0.50 in and 1.00 in of Wet Snow, or
  - Between 2.00 in and 4.00 in of Dry Snow.

For more information about equivalences, *Refer to PER-TOF-CTA Equivalences for Performance* .

L2 For takeoff performance assessment, in the case of Fluid Contaminant (Water, Slush), the contaminant depth has a dual effect on performance. The contaminant drag has a negative effect on the acceleration part, but a favorable effect on the deceleration segment. So, the takeoff performance for the higher contaminant depth is not systematically conservative versus the lower depth one.
When the flight crew performs a takeoff performance computation with a runway condition of ”Slush 1/2” (12.7 mm)”, T.O PERF automatically performs a second computation with a runway condition of ”Slush 1/4” (6.3 mm)” and chooses the more penalizing results (lower MTOW(PERF)).

L1 **COMPACTED SNOW**

The flight crew selects “Compacted snow” for runways covered with Compacted Snow.

ANTI-ICE

Applicable to: ALL

GENERAL

The engine bleed air system supplies high-pressure air to the following systems:
- Air conditioning and cabin pressurization
- Wing anti-ice and engine anti-ice
- Engine start
- Hydraulic reservoir pressurization
- Pack bay ventilation system.

L2 For more information about the engine bleed air system, *Refer to DSC-36-10-20-10 Engine Bleed Air System* .

L1 The air conditioning and the anti-ice (wing, engine) systems affect the takeoff performance. The engine bleeds reduce the available engine power. As a result, the takeoff distance increases and the takeoff climb gradient decreases.
The FADEC compensates to a large extent the thrust loss due to “Engine only” anti-ice.

T.O PERF

The flight crew selects one of the following setting from the A-ICE drop-down list:
- Off
- Engine only
- Engine & Wing.

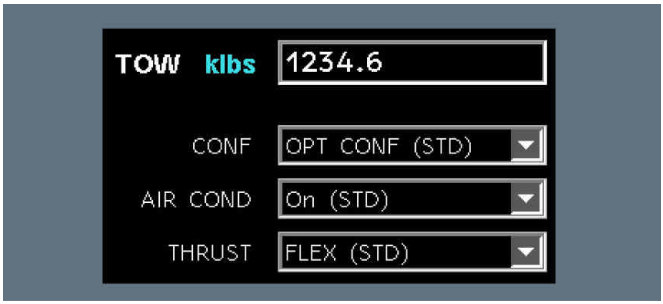
AIRCRAFT CONFIGURATION SUBPANEL

Applicable to: ALL

The Aircraft Configuration subpanel provides the following information:

- Takeoff Weight (TOW)
- Aerodynamic configuration
- Airflow
- Thrust option.

Aircraft Configuration Subpanel



TAKEOFF WEIGHT

Applicable to: ALL
Impacted by TDU: 00021444 Takeoff Weight

GENERAL

The actual takeoff weight must not exceed:
- The certified Maximum Takeoff Weight (MTOW), and
- MTOW(perf).

L2 For more information about MTOW(perf), *Refer to PER-TOF-TOR-SRS Takeoff Weights*.

L1 T.O PERF

The flight crew enters the desired TOW value.
The flight crew can use the shortcut "*" to insert the MTOW .
It is possible to enter a weight that is higher than the certified MTOW . The results will be displayed for the entered weight, regardless of the MTOW .

COMMUNICATION FROM LOADSHEET TO T.O PERF

When the flight crew has launched a LOADSHEET computation and then switches to T.O PERF, the TOW value is retrieved from the LOADSHEET results and is displayed in yellow in the CONDITIONS panel of T.O PERF.

TAKEOFF WEIGHT

Applicable to: ALL
Impacted DU: 00006199 Takeoff Weight

GENERAL

The actual takeoff weight must not exceed:
- The certified Maximum Takeoff Weight (MTOW), and
- MTOW(perf).

L2 For more information about MTOW(perf), *Refer to PER-TOF-TOR-SRS Takeoff Weights .*

L1 T.O PERF

The flight crew enters the desired TOW value.
The flight crew can use the shortcut "*" to insert the MTOW .
It is possible to enter a weight that is higher than the certified MTOW . The results will be displayed for the entered weight, regardless of the MTOW .

CAUTION	For some calculation sequences with at least two computations, when the flight crew enters the TOW in klbs, T.O PERF may use a lower TOW value. Workaround: Enter the TOW value directly in lb.

COMMUNICATION FROM LOADSHEET TO T.O PERF

When the flight crew has run a LOADSHEET computation and then switches to T.O PERF, the TOW value is retrieved from the LOADSHEET results and is displayed in yellow in the CONDITIONS panel of T.O PERF.

L2 *Note: There is a different rounding between LOADSHEET and T.O PERF: the TOW may be different by 100 lb . The TOW in T.O PERF is rounded up to the next 100 lb .*

AERODYNAMIC CONFIGURATION

Applicable to: ALL

GENERAL

The certified takeoff configurations are:
- CONF 1+F
- CONF 2
- CONF 3.

L2 For more information about takeoff configurations, *Refer to DSC-27-20-20 Configuration* .

L1 The selection of an aerodynamic configuration affects all takeoff performance limitations. The effects are multiple and complex.

L2 A higher flap setting will increase lift at a given speed, but will also increase drag. Therefore, a higher flap setting will improve takeoff performance, but will also degrade climb performance. As a result, it is recommended to use the following settings, in accordance with the applicable outside conditions:

OUTSIDE CONDITIONS	FLAP SETTING	OBJECTIVE
Well-paved runway (dry or wet)	Use the flap setting that provides the optimum performance. If takeoff weight is not limited by performance, consider using a higher flap setting.	To extend engine life and save maintenance costs, and improve aft fuselage clearance.
High altitude takeoff	Use CONF 2 or CONF 3.	To improve comfort.
Badly-paved runway, or accelerate stop limited runway	Use CONF 2 or CONF 3.	To improve comfort, and stopping distance.

L1 T.O PERF

Two types of calculation relating to aerodynamic configurations are available in T.O PERF:
- For a given flap setting (CONF 1+F ; CONF 2 ; CONF 3)
- OPT CONF.

When OPT CONF is selected, the optimum aerodynamic configuration for maximum weight (or maximum flexible temperature) is determined in the RESULTS panel.

AIRFLOW

Applicable to: ALL

GENERAL

The engine bleed air system supplies high-pressure air to the following systems:
- Air conditioning and cabin pressurization
- Wing anti-ice and engine anti-ice
- Engine start
- Hydraulic reservoir pressurization
- Pack bay ventilation system.

L2 For more information about the engine bleed air system, *Refer to DSC-36-10-20-10 Engine Bleed Air System* .

L1 The air conditioning and the anti-ice (wing, engine) systems affect the takeoff performance. The engine bleeds reduce the available engine power. As a result, the takeoff distance increases and the takeoff climb gradient decreases.

T.O PERF

The flight crew selects one of the following setting from the AIR COND drop-down list:
- On
- Off.

THRUST OPTION

Applicable to: ALL

GENERAL

Various thrust options are certified for takeoff.

In specific conditions, an optimum thrust can be found to achieve:
- The maximum performance limited takeoff weight
- The maximum thrust reduction to save engine life.

The use of a specific option depends on the outside conditions.

L2 For more information about thrust options:
- *Refer to TOGA*
- *Refer to FLEX Takeoff*
- *Refer to Derated Takeoff* .

L1 T.O PERF

T.O PERF provides four types of THRUST options:
- TOGA
- FLEX
- Derate level (D04, D08, D12, D16, D20, D24)
- OPTIMUM DERATE, for a takeoff at optimum thrust.

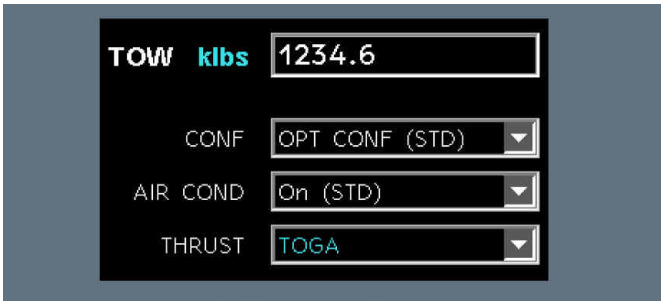
AIRCRAFT CONFIGURATION SUBPANEL

Applicable to: ALL

The Aircraft Configuration subpanel provides the following information:

- Takeoff Weight (TOW)
- Aerodynamic configuration
- Airflow
- Thrust option.

Aircraft Configuration Subpanel



TAKEOFF WEIGHT

Applicable to: ALL
Impacted by TDU: 00021445 Takeoff Weight

GENERAL

The actual takeoff weight must not exceed:
- The certified Maximum Takeoff Weight (MTOW), and
- MTOW(perf).

L2 For more information about MTOW(perf), *Refer to PER-TOF-TOR-MRS Takeoff Weights*.

L1 T.O PERF

The flight crew enters the desired TOW value.
The flight crew can use the shortcut "*" to insert the MTOW .
It is possible to enter a weight that is higher than the certified MTOW . The results will be displayed for the entered weight, regardless of the MTOW .

COMMUNICATION FROM LOADSHEET TO T.O PERF

When the flight crew has launched a LOADSHEET computation and then switches to T.O PERF, the TOW value is retrieved from the LOADSHEET results and is displayed in yellow in the CONDITIONS panel of T.O PERF.

TAKEOFF WEIGHT

Applicable to: ALL
Impacted DU: 00008698 Takeoff Weight

GENERAL

The actual takeoff weight must not exceed:
- The certified Maximum Takeoff Weight (MTOW), and
- MTOW(perf).

L2 For more information about MTOW(perf), *Refer to PER-TOF-TOR-MRS Takeoff Weights* .

L1 T.O PERF

The flight crew enters the desired TOW value.
The flight crew can use the shortcut "*" to insert the MTOW .
It is possible to enter a weight that is higher than the certified MTOW . The results will be displayed for the entered weight, regardless of the MTOW .

CAUTION	For some calculation sequences with at least two computations, when the flight crew enters the TOW in klbs, T.O PERF may use a lower TOW value. Workaround: Enter the TOW value directly in lb.

COMMUNICATION FROM LOADSHEET TO T.O PERF

When the flight crew has run a LOADSHEET computation and then switches to T.O PERF, the TOW value is retrieved from the LOADSHEET results and is displayed in yellow in the CONDITIONS panel of T.O PERF.

L2 *Note: There is a different rounding between LOADSHEET and T.O PERF: the TOW may be different by 100 lb . The TOW in T.O PERF is rounded up to the next 100 lb .*

AERODYNAMIC CONFIGURATION

Applicable to: ALL

GENERAL

The certified takeoff configurations are:
- CONF 1+F
- CONF 2
- CONF 3.

L2 For more information about takeoff configurations, *Refer to DSC-27-20-20 Configuration* .

L1 The selection of an aerodynamic configuration affects all takeoff performance limitations. The effects are multiple and complex.

L2 A higher flap setting will increase lift at a given speed, but will also increase drag. Therefore, a higher flap setting will improve takeoff performance, but will also degrade climb performance. As a result, it is recommended to use the following settings, in accordance with the applicable outside conditions:

OUTSIDE CONDITIONS	FLAP SETTING	OBJECTIVE
Well-paved runway (dry or wet)	Use the flap setting that provides the optimum performance. If takeoff weight is not limited by performance, consider using a higher flap setting.	To extend engine life, and improve aft fuselage clearance.
High altitude takeoff	Use CONF 2 or CONF 3.	To improve comfort.
Badly-paved runway, or accelerate stop limited runway	Use CONF 2 or CONF 3.	To improve comfort, and stopping distance.

L1 T.O PERF

Two types of calculation relating to aerodynamic configurations are available in T.O PERF:
- For a given flap setting (CONF 1+F ; CONF 2 ; CONF 3)
- OPT CONF.

When OPT CONF is selected, the optimum aerodynamic configuration for maximum weight (or maximum flexible temperature) is determined in the RESULTS panel.

AIRFLOW

Applicable to: ALL

GENERAL

The engine bleed air system supplies high-pressure air to the following systems:
- Air conditioning and cabin pressurization
- Wing anti-ice and engine anti-ice
- Engine start
- Hydraulic reservoir pressurization
- Pack bay ventilation system.

L2 For more information about the engine bleed air system, *Refer to DSC-36-10-20-10 Engine Bleed Air System* .

L1 The air conditioning and the anti-ice (wing, engine) systems affect the takeoff performance. The engine bleeds reduce the available engine power. As a result, the takeoff distance increases and the takeoff climb gradient decreases.

T.O PERF

The flight crew selects one of the following setting from the AIR COND drop-down list:
- On
- Off.

THRUST OPTION

Applicable to: ALL

GENERAL

Various thrust options are certified for takeoff.

In specific conditions, an optimum thrust can be found to achieve:
- The maximum performance limited takeoff weight
- The maximum thrust reduction to save engine life.

The use of a specific option depends on the outside conditions.

L2 For more information about thrust options:
- *Refer to TOGA*
- *Refer to FLEX Takeoff*
- *Refer to Derated Takeoff* .

L1 T.O PERF

T.O PERF provides three types of THRUST options:
- TOGA
- Derate level (D04, D08, D12, D16, D20, D24)
- OPTIMUM DERATE, for a takeoff at optimum thrust.

AIRCRAFT STATUS PANEL

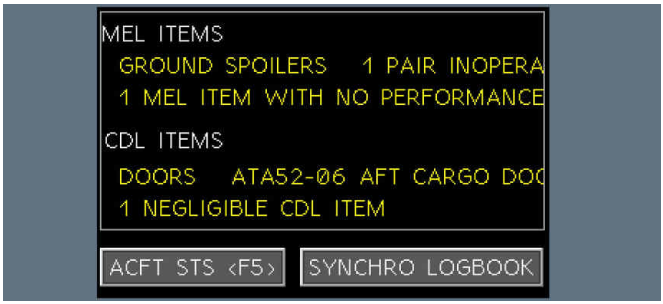
Applicable to: ALL

The current aircraft status must be considered during flight preparation.

The reminder area of the AIRCRAFT STATUS panel lists:
- Inoperative systems impacting takeoff performance
- The number of MEL items without takeoff performance impact (if any)
- CDL items impacting takeoff performance
- The number of negligible CDL items (if any).

If the aircraft is dispatched without any deferred items, "NO PERFORMANCE IMPACT" appears in the reminder area of the AIRCRAFT STATUS panel.

Reminder area of the AIRCRAFT STATUS Panel



SYNCHRO LOGBOOK

The flight crew can recover the eLogbook status by clicking on the "SYNCHRO LOGBOOK" button.
For more information about the SYNCHRO LOGBOOK function, *Refer to PER-TOF-TOC-AFS Synchronization with Logbook* .

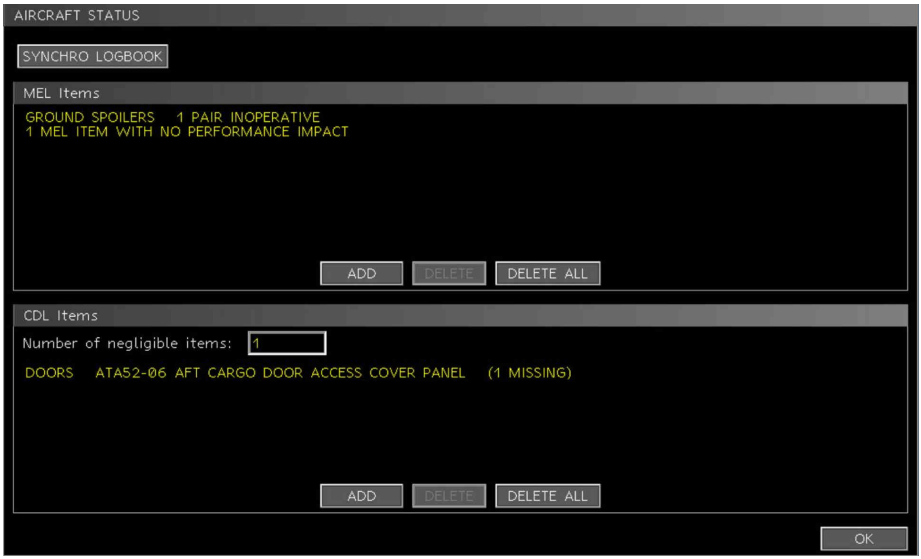
AIRCRAFT STATUS

By clicking on the ACFT STS button, the flight crew opens the AIRCRAFT STATUS panel.

The AIRCRAFT STATUS panel is divided in two subpanels:
- MEL items
- CDL items.

Moreover, the flight crew can recover the eLogbook status by clicking on the "SYNCHRO LOGBOOK" button.

AIRCRAFT STATUS Panel



MEL

Applicable to: ALL

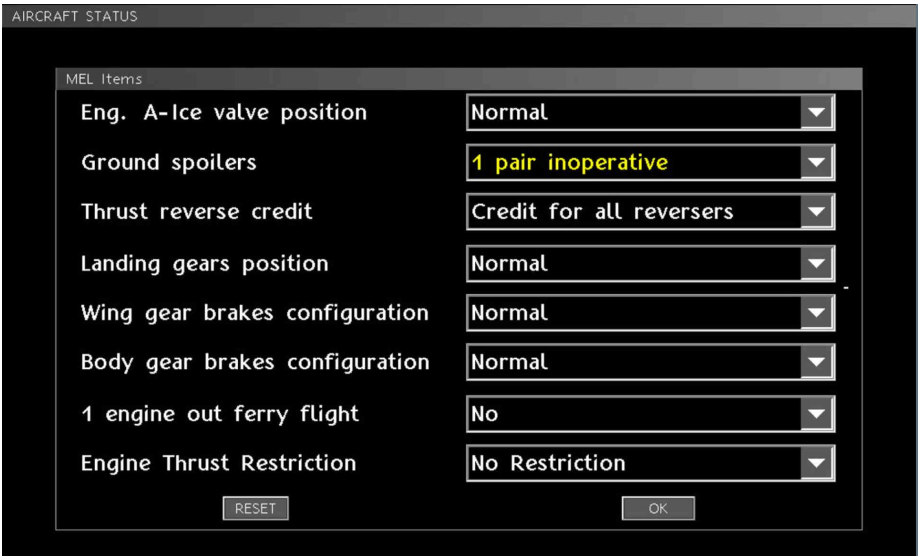
The MEL items subpanel displays the inoperative systems selected by the flight crew using:

- The OPS LIBRARY / MEL manual, via the selection of a MEL item, or
  In this case, the inoperative systems are displayed in yellow on T.O PERF.
- The T.O PERF MEL panel.
  In this case, the inoperative systems are displayed in cyan on T.O PERF.

MEL ITEM SELECTION

To open the MEL items panel, the flight crew uses the ADD button of the MEL items subpanel.
The MEL items panel displays the list of systems that could be inoperative and that involve takeoff performance penalties.
The flight crew selects inoperative items by selecting the appropriate status for each item in the drop-down lists.
The inoperative systems associated to the MEL item are described in the (o) procedure of the MEL item.

MEL Items Panel



The selected item appears in the MEL items subpanel and in the reminder area of the AIRCRAFT STATUS panel.

MEL ITEMS COMBINATION

The flight crew must check that the MEL items combination is permitted for dispatch in the "MEL Items" section of the MEL manual.
T.O PERF does not ensure that the selected combination of inoperative systems is permitted for dispatch.

COMMUNICATION BETWEEN MEL MANUAL AND T.O PERF

When the aircraft is dispatched with MEL items and if these MEL items are selected via the OPS LIBRARY / MEL manual:

- The associated inoperative systems that affect the takeoff performance are automatically selected and displayed in yellow on the reminder area of the AIRCRAFT STATUS panel in T.O PERF
- The number of MEL items without takeoff performance impact is displayed in yellow on the reminder area of the AIRCRAFT STATUS panel in T.O PERF.

Some MEL items induce a restriction on the use of the derated or flexible takeoff thrust.
If such a MEL item is selected via the OPS LIBRARY / MEL manual, T.O PERF automatically applies the associated thrust restriction.

LIMITATION

If the flight crew directly selects the inoperative system "1 engine out ferry flight" in the AIRCRAFT STATUS panel of T.O PERF, T.O PERF does not automatically applies the thrust restriction associated to this inoperative system.
Workaround: The flight crew must manually select the correct engine thrust in the THRUST drop down list of the CONDITIONS panel.

ENG. A-ICE VALVE POSITION

Calculation may fail when the MEL item "Eng. A-Ice valve position: Stuck open" is selected.

In the case of calculation failure when the MEL item "Eng. A-Ice valve position: Stuck open" is selected, the flight crew must:

- Deselect the MEL item "Eng. A-Ice valve position: Stuck open"
- Select "Engine & Wing" in the A-ICE drop down list of the CONDITIONS panel.

This workaround calculates correctly and yields the correct results.

CDL

Applicable to: ALL

The CDL items subpanel displays the missing structural parts selected by the flight crew using:

- The OPS LIBRARY / CDL manual, via the selection of a CDL item, or
  In this case, the CDL items are displayed in yellow on T.O PERF.
- The T.O PERF CDL panel.
  In this case, the CDL items are displayed in cyan on T.O PERF.

The CDL items subpanel also displays the number of negligible items.

NUMBER OF NEGLIGIBLE ITEMS

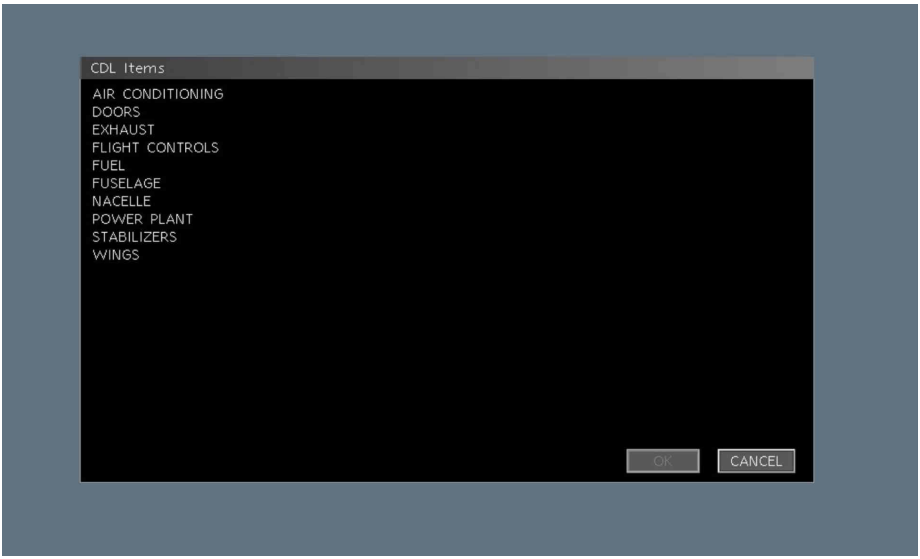
The flight crew enters the number of different structural parts simultaneously missing that have a negligible impact on the performance.

L2 If the number of negligible items is less or equal to three, then no penalty applies. If the number of negligible items is greater or equal to four, then a drag increase for each item is applied.
For more information about the negligible CDL items, *Refer to AFM/MCDL-GEN-PERF Performance penalties published in the Airplane Flight Manual MCDL chapter*.

L1 CDL ITEM SELECTION

To open the CDL items panel, the flight crew uses the ADD button of the CDL items subpanel. The CDL items panel displays the list of structural parts that could be missing and that involve takeoff performance penalties.

CDL items Panel



To add a CDL item, the flight crew selects:
- The appropriate system group
- The corresponding CDL item
- The number of items missing

The selected item appears in the CDL items subpanel and in the reminder area of the AIRCRAFT STATUS panel.

Note: *When the flight crew selects a CDL item, the number of missing items is hidden in the ACFT STS box. The flight crew must use the scroll bar to display the hidden information.*

CDL ITEMS COMBINATION

The flight crew must check that the CDL items combination is permitted for dispatch in the Aircraft Flight Manual (AFM).
T.O PERF does not ensure that the selected configuration is permitted for dispatch.

COMMUNICATION BETWEEN CDL MANUAL AND T.O PERF

When the aircraft is dispatched with CDL items and if these CDL items are selected via the OPS LIBRARY / CDL manual:

- The CDL items that affect the takeoff performance are automatically selected and displayed in yellow on the reminder area of the AIRCRAFT STATUS panel in T.O PERF. Their associated number of missing parts is also displayed.
- The number of CDL items without takeoff performance impact is displayed in yellow on the reminder area of the AIRCRAFT STATUS panel in T.O PERF. These CDL items are called "negligible items".

When the flight crew uses the OPS LIBRARY / CDL manual to select a specific CDL item that affects the takeoff performance and then starts T.O PERF, the takeoff performance module may consider this CDL item as a negligible item if the CDL To T.O PERF communication file does not include this CDL item.
In this case, the flight crew must manually apply the weight reduction described in the OPS LIBRARY / CDL manual to the MTOW(PERF) calculated by T.O PERF.

SYNCHRONIZATION WITH LOGBOOK

Applicable to: ALL

The flight crew can recover the eLogbook status by clicking on the "SYNCHRO LOGBOOK" button. This action synchronizes the aircraft status of the whole FLT OPS domain with the current deferred items of the eLogbook
If the flight crew had previously selected additional MEL and CDL items in T.O PERF (displayed in cyan in the AIRCRAFT STATUS panel) and then uses the SYNCHRO LOGBOOK function, these manually entered items are lost.

Note: *1. When the flight crew uses the SYNCHRO LOGBOOK function in T.O PERF, the whole FLT OPS domain is also synchronized with the eLogbook*
2. If the Logbook status is lost in the FLT OPS domain, T.O PERF may synchronize with an old Logbook status.

Intentionally left blank

RESULTS DATA

Applicable to: ALL

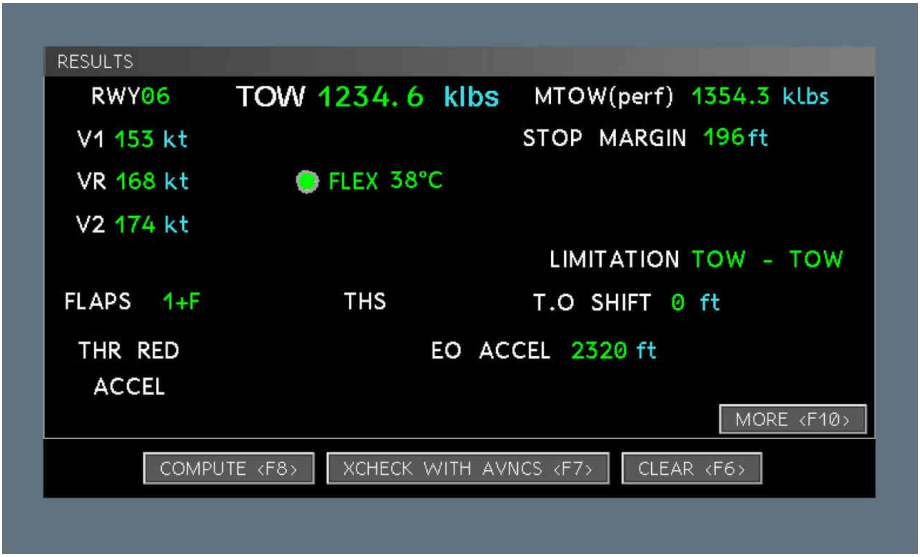
GENERAL

A takeoff performance calculation computes the following results:

- The takeoff weights
- The takeoff speeds
- The power
- The stop margin
- The aerodynamic configuration
- The limitation codes
- The engine-out acceleration altitude.

T.O PERF

RESULTS Panel



TAKEOFF WEIGHTS

Applicable to: ALL

GENERAL

The Maximum Takeoff Weight Limited by the Performance (MTOW(PERF)) is the maximum aircraft weight which complies with all the regulatory requirements for takeoff performance in given environmental conditions.
The MTOW(PERF) value may exceed the certified MTOW value. However, the real takeoff weight must not exceed MTOW .

L2 For a relevant value of MTOW , *Refer to FCOM Limitations* .

L1 T.O PERF

The RESULTS panel displays the following two weights:
- TOW, the input weight of the calculation
- MTOW(perf).

COMMUNICATION FROM T.O PERF TO LOADSHEET

When the flight crew completes a T.O PERF computation and then changes from T.O PERF to LOADSHEET, T.O PERF transfers the calculated MTOW(PERF) value to LOADSHEET if the MTOW(PERF) value is lower than or equal to the certified MTOW value. If the MTOW(PERF) value is transferred, LOADSHEET displays this value in yellow in the MTOW field of the CONDITIONS panel.

TAKEOFF SPEEDS

Applicable to: ALL

GENERAL

For a specific runway and in defined conditions, the takeoff performance optimization process determines the optimum takeoff speeds, in order to maximize the takeoff weight and Flexible Temperature (TFLEX), by taking into account the regulatory requirements.

L2 DECISION SPEED - V1

The decision speed is referred to as V1.
V1 is the maximum speed at which the flight crew can reject the takeoff in the case of engine failure, in such a way that the aircraft is still able to stop within the runway limits.

The takeoff optimization computation considers that:
- The engine failure occurs 1 second before V1
- The decision to abort takeoff occurs at V1.

V1 must be at least equal to the minimum control speed on ground (VMCG) plus 1 second acceleration on the remaining engines.
Depending on takeoff performance limitations, the V1 that results from the speed optimization can either be a single value or a range of values.
For more information about speed optimization, *Refer to PER-TOF-GEN Speed Optimization* .

In the case of a V1 range, the Operator can use one of the following three options:
- V1 min:
  - Is the lowest permitted decision speed
  - Provides the best stop margin
    For more information about stop margin, *Refer to PER-TOF-TOR-SRS Stop Margin* .
  - But increases the go-distance time between V1 and VR.
- V1 max:
  - Is the highest permitted takeoff decision speed
  - Reduces the go-distance time between V1 and VR
  - But provides the lowest stop margin.
- V1 mean:
  - Is a compromise between V1 min and V1 max.

ROTATION SPEED - VR

VR is the speed at which the flight crew must initiate the rotation.

VR may not be less than:
- V1
- 105 % of the minimum control speed in the air (VMCA)
- The speed that allows reaching V2 before reaching a height of 35 ft above the runway.

In addition the liftoff speed (VLOF), that results from VR, must:
- Be lower than the maximum tire speed (VTIRE)
- Exceed the minimum unstick speed (VMU) OEI by 4 % and AEO by 8 % .

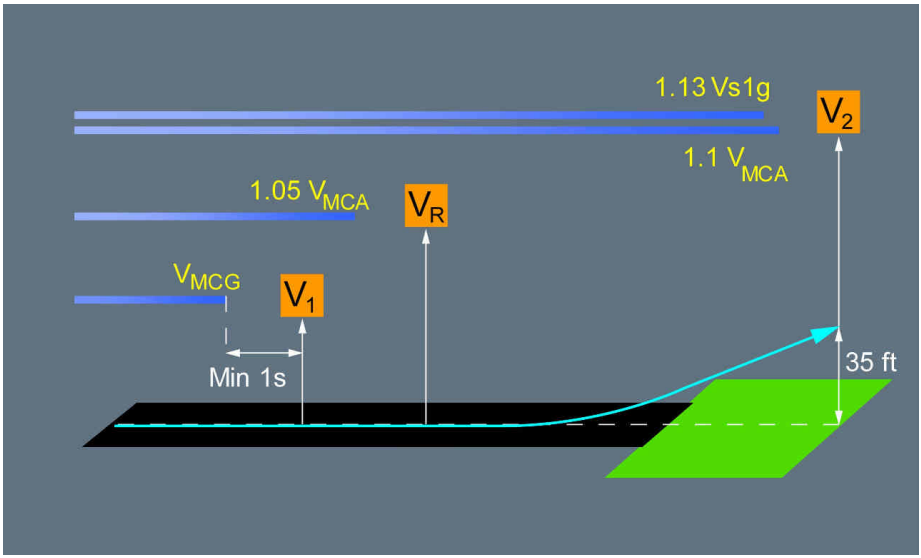
MINIMUM TAKEOFF CLIMB SPEED - V2

If one engine fails, the aircraft must reach the minimum takeoff climb speed at a height of 35 ft above the runway. This minimum takeoff climb speed is referred to as V2.

V2 must exceed:
- The minimum control speed in the air (VMCA) by a minimum of 10 %
- The 1g stall speed (VS1G) by a minimum of 13 % .

L1 **SPEED SUMMARY**

Takeoff Speeds Summary



T.O PERF

T.O PERF displays the following takeoff speeds on the RESULTS panel:
- V1, the decision speed
- VR, the rotation speed
- V2, the minimum takeoff climb speed.

In the case of a V1 range resulting from the speed optimization process, the following two display modes are available:

SINGLE V1

Single V1

Only one V1 value is displayed and can correspond to:
- V1 min, or
- V1 max, or
- V1 mean.

V1 RANGE

V1 Range

The V1 value may be selected within the [V1 min ; V1 max] range via arrow keys.

THRUST

Applicable to: ALL

Depending on the THRUST option that the flight crew has selected on the CONDITIONS panel, the thrust label displayed on the RESULTS panel may be:

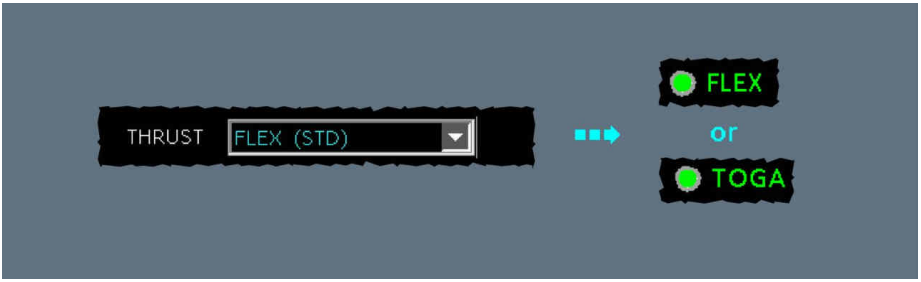
- The selected THRUST option, if TOGA or a derate level (D04, D08, etc.) was selected
- An optimum derate level, if OPTIMUM DERATE was selected
- An adapted thrust to the actual takeoff weight, if FLEX was selected.

THRUST Option

FLEX TAKEOFF

Applicable to: ALL

FLEX THRUST Option



WHEN FLEX TAKEOFF IS POSSIBLE

The Flexible Temperature (TFLEX) is displayed if all the following conditions are met:

- FLEX is selected as the THRUST option
- FLEX Takeoff is permitted for the current runway conditions
- TOW is lower than MTOW(perf)
- There is TFLEX above TREF for TOW.

L2 For more information, *Refer to PER-TOF-THR-FLX TFLEX Possible Range* .

L1 WHEN FLEX TAKEOFF IS NOT POSSIBLE

TOGA thrust is displayed.

OPTIMUM DERATE

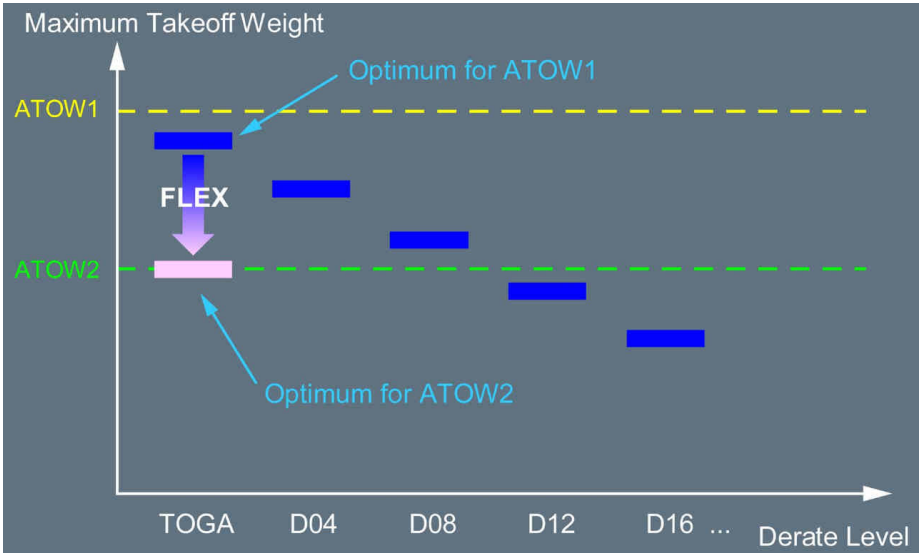
Applicable to: ALL

CAUTION	The use of derate levels lower than the one leading to the highest possible maximum performance limited takeoff weight is not permitted.

Note: *A lower derate level is a derate level that results in a higher thrust reduction.*

WITHOUT VMC LIMITATION

Optimum Derate Without VMC Limitation



ATOW1 CASE

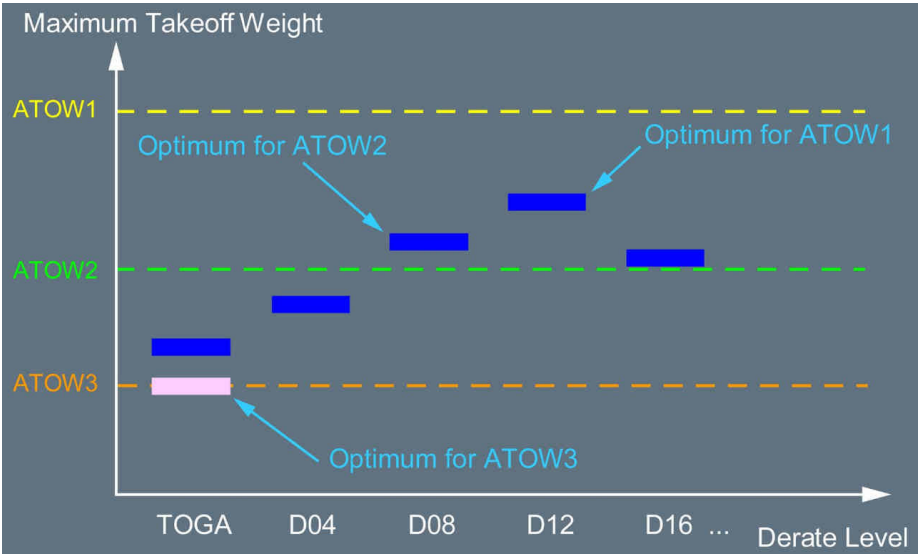
TOGA is displayed as the optimum derate level, even if it is not possible to takeoff (MTOW(perf) lower than ATOW1).

ATOW2 CASE

TOGA is the optimum derate level.
If FLEX Takeoff is permitted, TFLEX is displayed.

WITH VMC LIMITATION

Optimum Derate With VMC Limitation



ATOW1 CASE

D12 is displayed as the optimum derate level, even if it is not possible to takeoff (MTOW(perf) lower than ATOW1).

ATOW2 CASE

D08 is displayed as the optimum derate level, even if it is allowed to takeoff with D12.
However, it is not permitted to takeoff using D16 in this example, even if it is theoretically possible to takeoff with this derate level.

ATOW3 CASE

TOGA is the optimum derate level.
If FLEX Takeoff is permitted, TFLEX is displayed.
However, it is allowed to takeoff with D04, D08 and D12 in this example.
It is still not permitted to takeoff using D16 in this example, even if it is theoretically possible to takeoff with this derate level.

STOP MARGIN

Applicable to: ALL

GENERAL

The stop margin is the difference between the Accelerate-Stop Distance (ASD) and the available runway length including the Stopway (SWY).

T.O PERF

The display of the stop margin depends on the V1 option:

STP MRG

STP MRG

Only one stop margin is displayed, if the V1 type is:
- A V1 min setting, or
- A V1 max setting.

STP MRG V1 MIN & STP MRG V1 MAX

STP MRG V1 Min & STP MRG V1 Max

Two stop margins are displayed, if the V1 type is:

- A V1 mean setting, or
- A range of V1 setting.

STP MRG V1 Min corresponds to the maximum stop margin (i.e. the stop margin calculated for the lowest permitted V1).
STP MRG V1 Max corresponds to the minimum stop margin (i.e. the stop margin calculated for the highest permitted V1).
In the case of a V1 mean setting, the stop margin V1 mean is closer to STP MRG V1 Max than STP MARG V1 Min.

TAKEOFF LIMITATION CODES

Applicable to: ALL

GENERAL

Several regulatory requirements limit takeoff performance. They are called takeoff limitations.

T.O PERF

The requirements that limit performance in specific cases are identified in the computation results via limitation codes.

Usually, MTOW(perf) is obtained at the intersection of two limitation curves. For this reason, the limitation codes are always indicated by two codes.

The two codes are identical if MTOW(perf) is only limited by one limitation.

The following table indicates the various codes that can appear:

TOW	Maximum computation weight, or maximum structural weight
RWY0	All-engine Takeoff Distance (TOD0)
	or All-engine Takeoff Run (TOR0)
	or All-engine Accelerate-Stop Distance (ASD0)
RWY1	One-engine Inoperative Takeoff Distance (TOD1)
	or One-engine Inoperative Takeoff Run (TOR1)
	or One-engine Inoperative Accelerate-Stop Distance (ASD1)
VMCG	V1 limited by Certified Minimum Control Speed on Ground
TIRE	Vlof limited by Maximum Tire Speed
BRK	V1 limited by Maximum Brake Energy
VMCA	V2 limited by certified Minimum Control Speed in the Air
1SEG	First Segment Climb Gradient
2SEG	Second Segment Climb Gradient
3SEG	Acceleration (third) Segment
FTO	Final Takeoff Climb Gradient
OBS	Obstacle Clearance
VMU	Minimum Unstick Speed

Customized codes may differ from the above listed.

AERODYNAMIC CONFIGURATION

Applicable to: ALL

GENERAL

For more information about aerodynamic configuration, *Refer to Aerodynamic Configuration (Input)* .

If the takeoff performance for two aerodynamic configurations is identical, the highest flap setting is recommended.

L2 The highest flap setting corresponds to the configuration that provides the lowest takeoff speeds and, therefore, improves safety during a rejected takeoff (RTO).

L1 T.O PERF

The FLAPS field on the RESULTS panel displays the selected or optimized configuration.

The optimization process keeps the configuration that provides the maximum performance limited takeoff weight (or the maximum TFLEX).

If the weight is the same for several configurations, the configuration that provides the lowest takeoff speeds is selected.

TAKEOFF SHIFT

Applicable to: ALL

GENERAL

The takeoff shift is a reduction of the takeoff distances (TORA, TODA, ASDA) due to a shifted entry of the aircraft on the runway.

T.O PERF

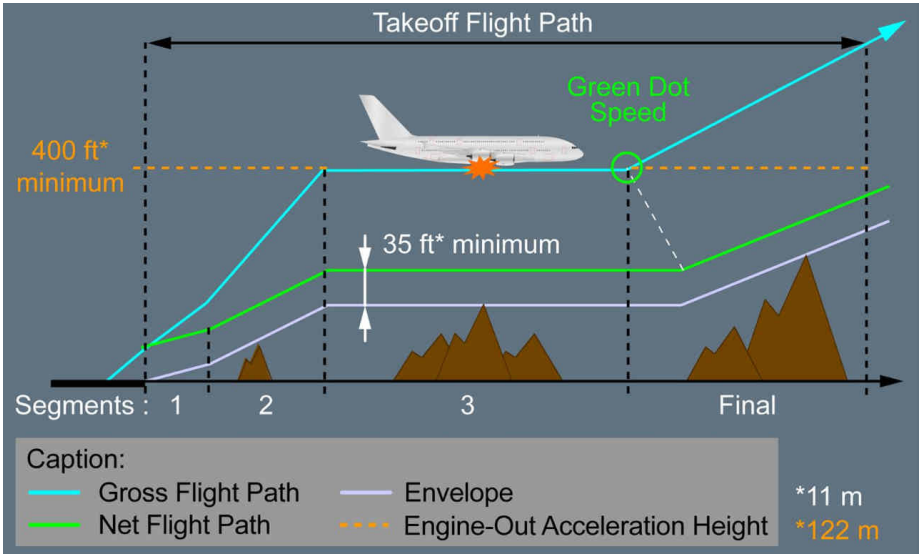
The RESULTS panel displays the takeoff shift (T.O SHIFT) of the SINGLE RWY COMPUTATION panel.

ENGINE-OUT ACCELERATION ALTITUDE

Applicable to: ALL

L2 GENERAL

Engine-Out Acceleration Height



The certified minimum acceleration height is 400 ft above the takeoff surface.
The gross minimum acceleration height ensures that the obstacles are cleared by the net takeoff flight path with the regulatory margin.
The maximum acceleration height ensures that acceleration to Green Dot speed and cleanup can be achieved within the maximum permitted 10 min of TOGA.

L1 T.O PERF

The EO ACCEL field on the RESULTS panel displays the computed engine-out acceleration altitude value.

Note: *This value is a pressure altitude.*

MORE PANEL

Applicable to: ALL

The MORE panel displays the following information:

- The results of the T.O PERF computation, identical to the results displayed on the RESULTS panel
- The thrust reverser status for the T.O PERF computation:
  - For dry and wet runway conditions, the thrust reverser status is: NO REVERSE THRUST CREDIT
  - For contaminated runways, the thrust reverser status is defined as per Operator policy.
- Additional results data that the Operator can customize.

MORE Panel

XCHECK WITH AVIONICS

Applicable to: ALL

The XCHECK WITH AVNCS function enables the flight crew to crosscheck the FMS takeoff performance entries with the OIS takeoff performance results.

L2 For more information about the XCHECK WITH AVNCS procedure, *Refer to PRO-NOR-SOP-60-B FMS INITIALIZATION_FMS DATA CROSSCHECK* .

L1 The following takeoff performance data are crosschecked:

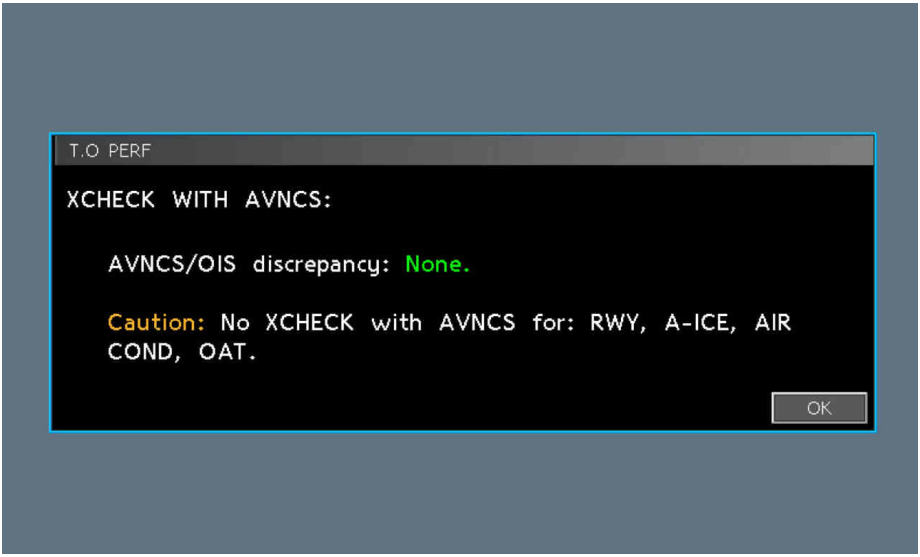
- Takeoff Speeds: V1, VR, V2
- Aerodynamic configuration (FLAPS)
- Takeoff weight (TOW)
- Flexible Temperature (TFLEX)
- QNH .

When the flight crew uses the XCHECK WITH AVNCS function, the crosscheck is performed with:

- The takeoff speeds, the aerodynamic configuration, the TOW , and thrust displayed on the RESULTS panel
- The QNH entered in the CONDITIONS panel.

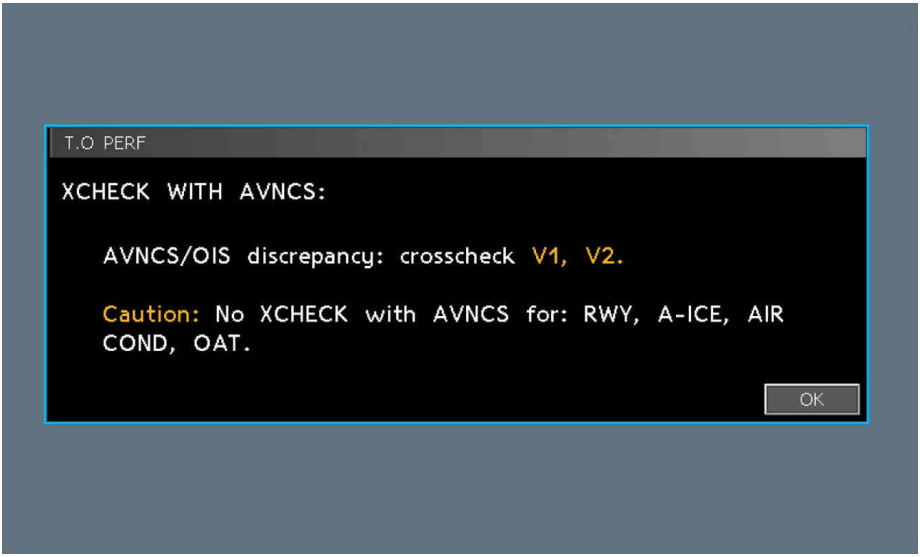
If there is no discrepancy between the FMS takeoff performance entries and the OIS takeoff performance results, T.O PERF displays the following popup message.

AVNCS/OIS: no Discrepancy



If there is one or more discrepancies between the FMS takeoff performance entries and the OIS takeoff performance results, T.O PERF displays the following popup message. The discrepancy parameters are displayed in amber (e.g. V1 and V2 in the following example).

AVNCS/OIS: Discrepancies



Note: *There is no crosscheck for the following parameters: RWY, A-Ice, AIR COND, OAT.*

XCHECK WITH AVNCS ASSUMPTIONS

TOW

The XCHECK WITH AVNCS function is active if and only if the calculated MTOW(perf) is equal to or above than the TOW value.
The XCHECK WITH AVNCS function compares the TOW value with the Gross Weight (GW) coming from the ECAM and displayed on the permanent data of the System Display (SD). Consequently, the TOW crosscheck does not make sense if it is performed before the end of the refueling.
The TOW crosscheck is successful if GW is included in the following weight range: 0.99*TOW ≤ GW ≤ 1.0035*TOW.

TAKEOFF SPEEDS

The VR/V2 crosscheck is successful if:
- The VR value inserted in the FMS T.O page is equal to the VR value calculated in T.O PERF
- The V2 value inserted in the FMS T.O page is equal to the V2 value calculated in T.O PERF.

Single V1

Single V1

The V1 crosscheck is successful if the V1 value inserted in the FMS T.O page is equal to the V1 value calculated in T.O PERF.

V1 Range

V1 Range

The V1 crosscheck is successful if the V1 value inserted in the FMS T.O page is selected within the [V1 min ; V1 max] range calculated in T.O PERF.

FLAPS

The FLAPS crosscheck is successful if the FLAPS selection on the FMS T.O page corresponds to the one selected or computed in T.O PERF.

QNH

The XCHECK WITH AVNCS function checks the QNH if and only if the barometric reference of the CM1 is QNH.
The QNH crosscheck is successful if the QNH displayed on the EFIS Control Panel of the CM1 (named CM1_QNH) is included in the following QNH range compared to the entered QNH in T.O PERF (named OIS_QNH): OIS_QNH - 0.99 hPa ≤ CM1_QNH ≤ OIS_QNH + 0.99 hPa.

XCHECK WITH AVNCS ASSUMPTIONS

THRUST

The Thrust crosscheck of the XCHECK WITH AVNCS function compares the Thrust selection of the FMS T.O page with the selected or calculated thrust in T.O PERF.
The Thrust crosscheck rules are expressed in the following matrix table:

XCHECK WITH AVNCS popup message		Thrust in FMS T.O page		
		TOGA	FLEX	DERATED
Thrust in T.O PERF results	TOGA	Caution: No XCHECK with AVNCS for: THRUST	AVNCS/OIS discrepancy: crosscheck THRUST	Caution: No XCHECK with AVNCS for: THRUST
	FLEX	AVNCS/OIS discrepancy: crosscheck THRUST	*Flexible Temperature comparison*	AVNCS/OIS discrepancy: crosscheck THRUST
	DERATED	Caution: No XCHECK with AVNCS for: THRUST	AVNCS/OIS discrepancy: crosscheck THRUST	Caution: No XCHECK with AVNCS for: THRUST

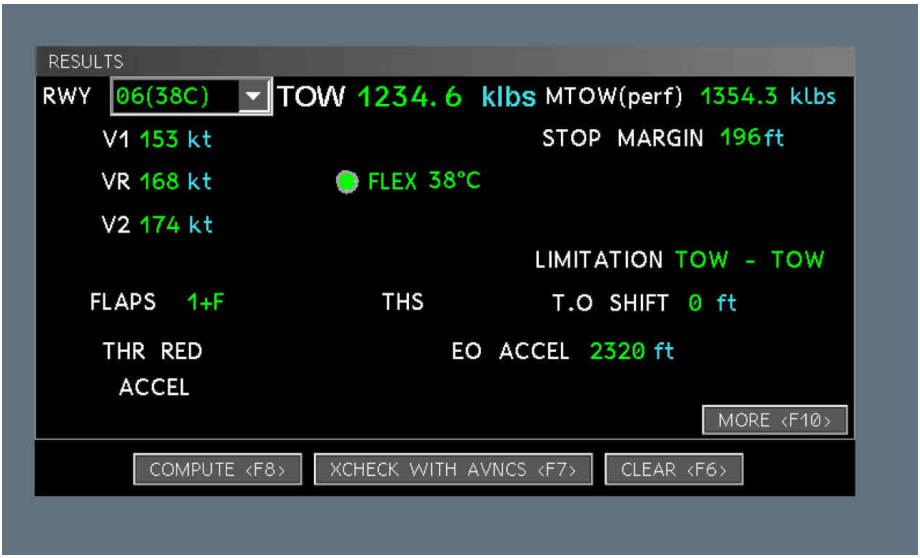
The FMS_FLEX vs. T.O PERF_FLEX check requires a flexible temperature comparison before displaying a XCHECK WITH AVNCS message.
In this case, the Thrust crosscheck of the XCHECK WITH AVNCS function compares the FLEX temperature value inserted in the FMS T.O page with the Flexible Temperature (TFLEX) value computed by T.O PERF.
This crosscheck is successful if the inserted FLEX temperature is included in the following temperature range: TFLEX - 5 °C ≤ FLEX ≤ TFLEX.
Otherwise, the XCHECK WITH AVNCS popup message displays "AVNCS/OIS discrepancy: crosscheck THRUST".

COMPUTATION RESULTS

Applicable to: ALL

The flight crew can access the results for each runway via the RWY drop-down list.

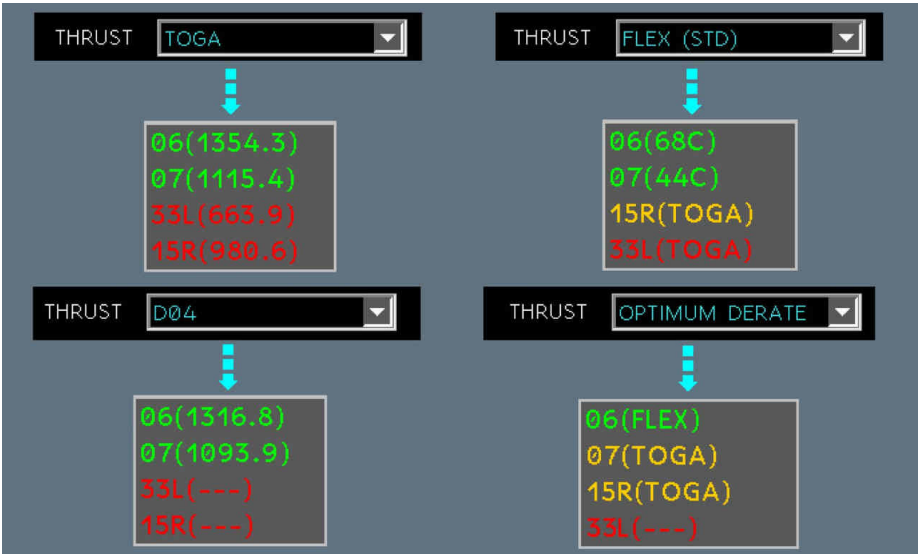
Single RESULTS Panel - MULTIPLE RWY COMPUTATION



MULTIPLE RWY COMPUTATION

Applicable to: ALL

Runway Selection



TOGA

For each runway, the maximum performance limited takeoff weight is displayed between brackets after the Runway ID.
The list is sorted by weight from the highest to the lowest and is color-coded.

GREEN

When MTOW(perf) is above, or equal to, TOW.

RED

When MTOW(perf) is below TOW.

DERATE

For each runway, the maximum performance limited takeoff weight is displayed between brackets after the Runway ID.
The list is sorted by weight from the highest to the lowest and is color-coded.

GREEN

When MTOW(perf) is above, or equal to, TOW.

RED

When MTOW(perf) is below TOW.

FLEX

For each runway, TFLEX (or TOGA when FLEX Takeoff is not permitted) is displayed between brackets after the Runway ID.
The list is sorted by temperature, then by weight (both in decreasing order). Moreover, it is color-coded.

GREEN

Indicates that the results correspond to a FLEX Takeoff.

AMBER

Indicates that the results correspond to a takeoff at TOGA, when MTOW(perf) is above, or equal to, TOW.

RED

Indicates that the results correspond to a takeoff at TOGA, when MTOW(perf) is below TOW.

OPTIMUM DERATE

For each runway, FLEX (or TOGA, or the derate level) is displayed between brackets after the Runway ID.
The list is sorted by temperature, then by weight (both in decreasing order). Moreover, it is color-coded.

GREEN

Indicates that the results correspond to FLEX Takeoff.

AMBER

Indicates that the results correspond to a takeoff at TOGA (or derate level), when MTOW(perf) is above, or equal to, TOW.

RED

Indicates that the results correspond to a takeoff at TOGA (or derate level), when MTOW(perf) is below TOW.

Intentionally left blank

RESULTS DATA

Applicable to: ALL

GENERAL

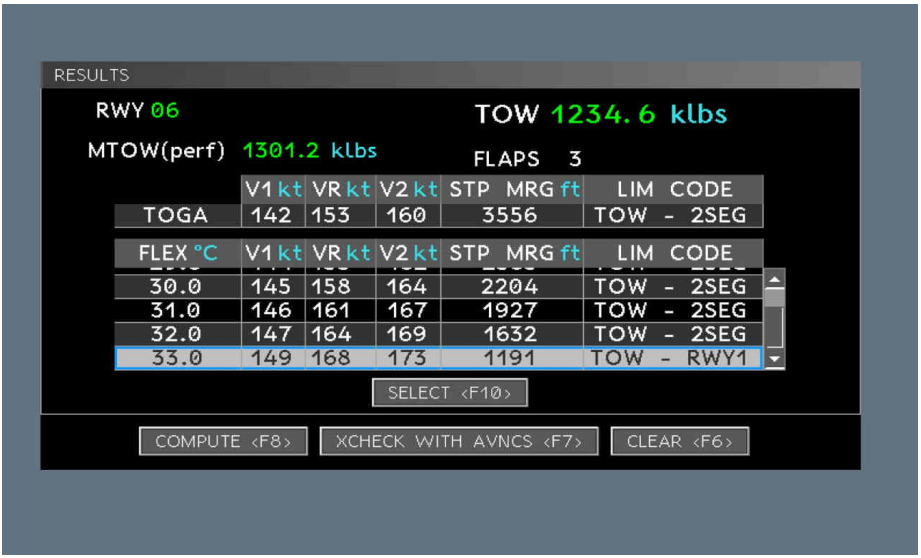
A takeoff performance calculation computes the following results:

- The takeoff weights
- The takeoff speeds
- The power
- The stop margin
- The aerodynamic configuration
- The limitation codes
- The engine-out acceleration altitude.

T.O PERF

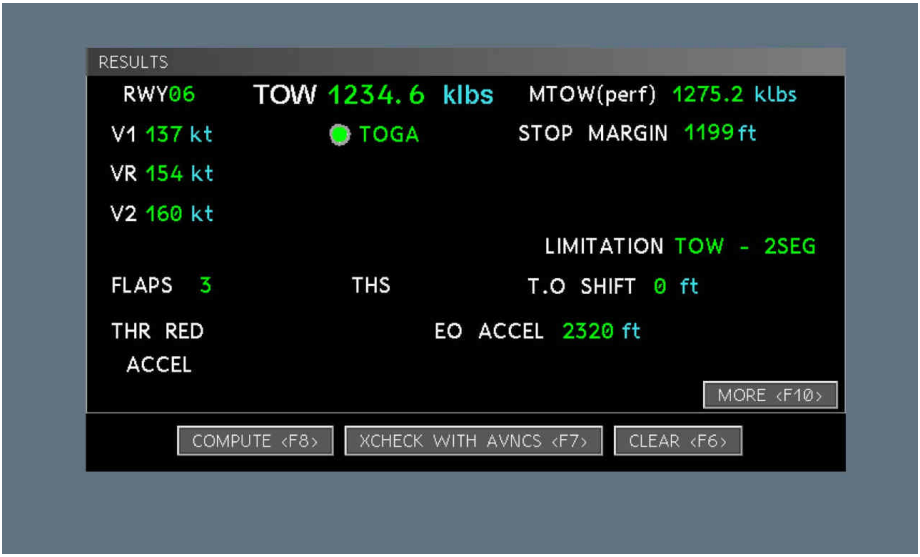
WHEN FLEX TAKEOFF IS POSSIBLE

RESULTS Panel



WHEN FLEX TAKEOFF IS NOT POSSIBLE

RESULTS Panel



TAKEOFF WEIGHTS

Applicable to: ALL

GENERAL

The Maximum Takeoff Weight Limited by the Performance (MTOW(PERF)) is the maximum aircraft weight which complies with all the regulatory requirements for takeoff performance in given environmental conditions.
The MTOW(PERF) value may exceed the certified MTOW value. However, the real takeoff weight must not exceed MTOW .

L2 For a relevant value of MTOW , *Refer to FCOM Limitations* .

L1 T.O PERF

The RESULTS panel displays the following two weights:
- TOW, the input weight of the calculation
- MTOW(perf).

COMMUNICATION FROM T.O PERF TO LOADSHEET

When the flight crew completes a T.O PERF computation and then changes from T.O PERF to LOADSHEET, T.O PERF transfers the calculated MTOW(PERF) value to LOADSHEET if the MTOW(PERF) value is lower than or equal to the certified MTOW value. If the MTOW(PERF) value is transferred, LOADSHEET displays this value in yellow in the MTOW field of the CONDITIONS panel.

TAKEOFF SPEEDS

Applicable to: ALL

GENERAL

For a specific runway and in defined conditions, the takeoff performance optimization process determines the optimum takeoff speeds, in order to maximize the takeoff weight and Flexible Temperature (TFLEX), by taking into account the regulatory requirements.

L2 **DECISION SPEED - V1**

The decision speed is referred to as V1.

The takeoff optimization computation considers that:
- The engine failure occurs 1 second before V1
- The decision to abort takeoff occurs at V1.

V1 must be at least equal to the minimum control speed on ground (VMCG) plus 1 second acceleration on the remaining engines.
Depending on takeoff performance limitations, the V1 that results from the speed optimization can either be a single value or a range of values.
For more information about speed optimization, *Refer to PER-TOF-GEN Speed Optimization* .

In the case of a V1 range, the Operator can use one of the following three options:
- V1 min:
  - Is the lowest permitted decision speed
  - Provides the best stop margin
    For more information about stop margin, *Refer to PER-TOF-TOR-MRS Stop Margin* .
  - But increases the go-distance time between V1 and VR.
- V1 max:
  - Is the highest permitted takeoff decision speed
  - Reduces the go-distance time between V1 and VR
  - But provides the lowest stop margin.
- V1 mean:
  - Is a compromise between V1 min and V1 max.

ROTATION SPEED - VR

VR is the speed at which the flight crew must initiate the rotation.

VR may not be less than:
- V1

- 105 % of the minimum control speed in the air (VMCA)
- The speed that allows reaching V2 before reaching a height of 35 ft above the runway.

In addition the liftoff speed (VLOF), that results from VR, must:
- Be lower than the maximum tire speed (VTIRE)
- Exceed the minimum unstick speed (VMU) OEI by 4 % and AEO by 8 % .

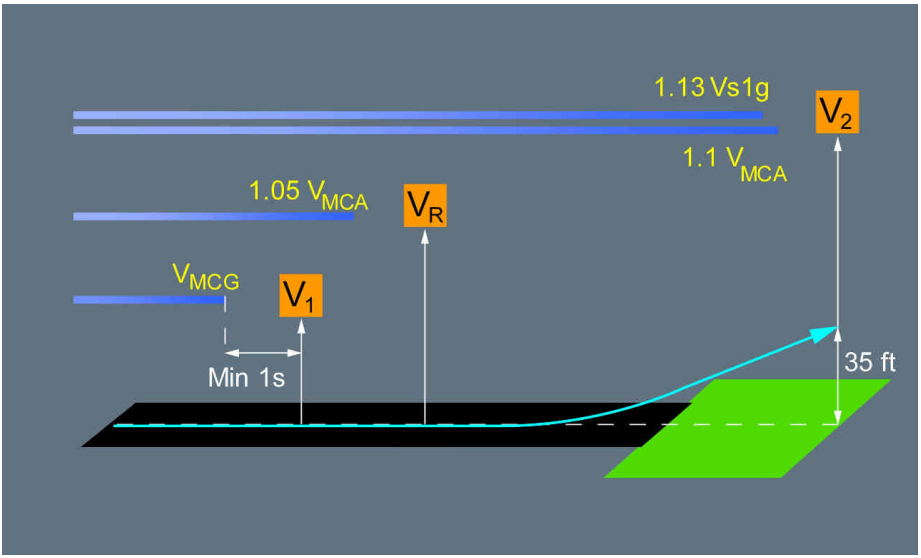
MINIMUM TAKEOFF CLIMB SPEED - V2

If one engine fails, the aircraft must reach the minimum takeoff climb speed at a height of 35 ft above the runway. This minimum takeoff climb speed is referred to as V2.

V2 must exceed:
- The minimum control speed in the air (VMCA) by a minimum of 10 %
- The 1g stall speed (VS1G) by a minimum of 13 % .

L1 **SPEED SUMMARY**

Takeoff Speeds Summary



T.O PERF

T.O PERF displays the following takeoff speeds on the RESULTS panel:
- V1, the decision speed
- VR, the rotation speed

- V2, the minimum takeoff climb speed.

In the case of a V1 range resulting from the speed optimization process, the following display modes are available.

WHEN FLEX TAKEOFF IS POSSIBLE

Single V1

Single V1

Only one V1 value is displayed and can correspond to:
- V1 min, or
- V1 max, or
- V1 mean.

V1 range

V1 Range

The following two values are displayed:
- V1 min
- V1 max.

WHEN FLEX TAKEOFF IS NOT POSSIBLE

Single V1

Single V1

Only one V1 value is displayed and can correspond to:
- V1 min, or
- V1 max, or
- V1 mean.

V1 range

V1 Range

The V1 value may be selected within the [V1 min ; V1 max] range via arrow keys.

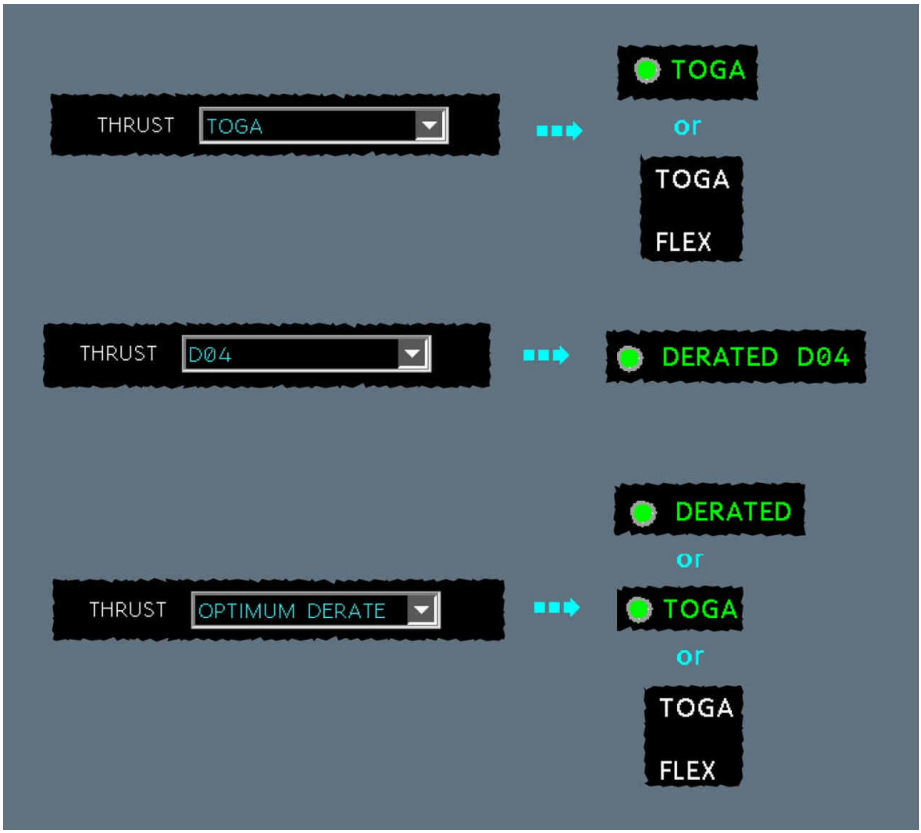
THRUST

Applicable to: ALL

Depending on the THRUST option that the flight crew has selected on the CONDITIONS panel, the thrust label displayed on the RESULTS panel may be:

- The selected THRUST option, if a derate level (D04, D08, etc.) was selected
- An optimum derate level, if OPTIMUM DERATE was selected
- An adapted thrust to the actual takeoff weight (FLEX or TOGA), if TOGA was selected.

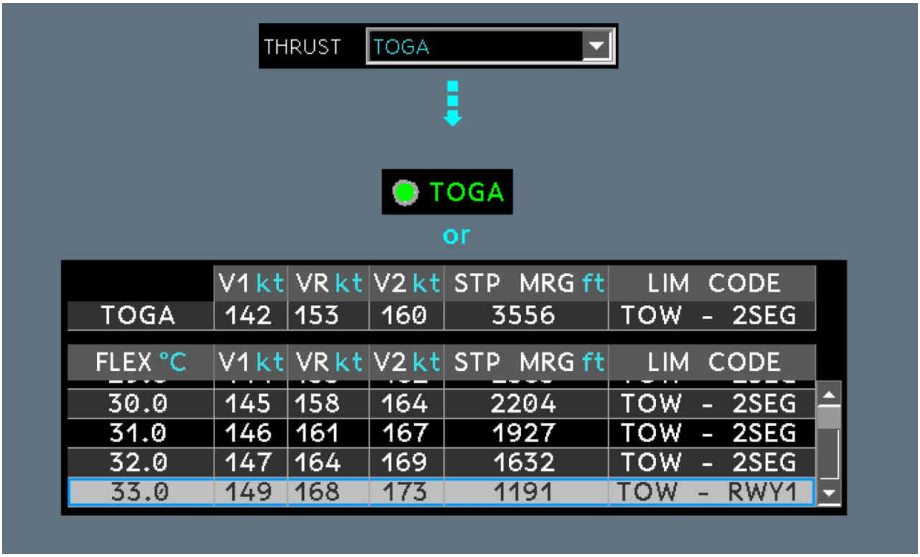
THRUST Option



FLEX TAKEOFF

Applicable to: ALL

TOGA THRUST Option



WHEN FLEX TAKEOFF IS POSSIBLE

Two tables are displayed if all the following conditions are met:

- TOGA is selected as the THRUST option
- FLEX Takeoff is permitted for the current runway conditions
- TOW is lower than MTOW(perf)
- There is TFLEX above TREF for TOW.

L2 For more information, *Refer to PER-TOF-THR-FLX TFLEX Possible Range* .

L1 **TOGA TABLE**

The TOGA table displays the associated takeoff data.

Note: *The TOGA result line is sometimes overlapped by the FLEX result line.*
Workaround: Move the cursor over the first line of the result table and select it.

FLEX TABLE

For each permitted TFLEX , the FLEX table displays its associated takeoff data.

WHEN FLEX TAKEOFF IS NOT POSSIBLE

TOGA thrust is displayed.

OPTIMUM DERATE

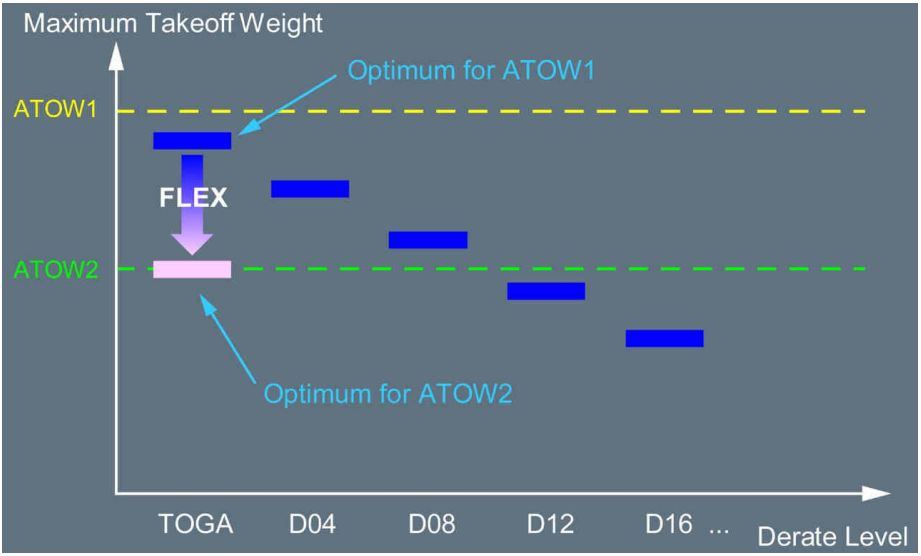
Applicable to: ALL

CAUTION	The use of derate levels lower than the one leading to the highest possible maximum performance limited takeoff weight is not permitted.

Note: *A lower derate level is a derate level that results in a higher thrust reduction.*

WITHOUT VMC LIMITATION

Optimum Derate Without VMC Limitation



ATOW1 CASE

TOGA is displayed as the optimum derate level, even if it is not possible to takeoff (MTOW(perf) lower than ATOW1).

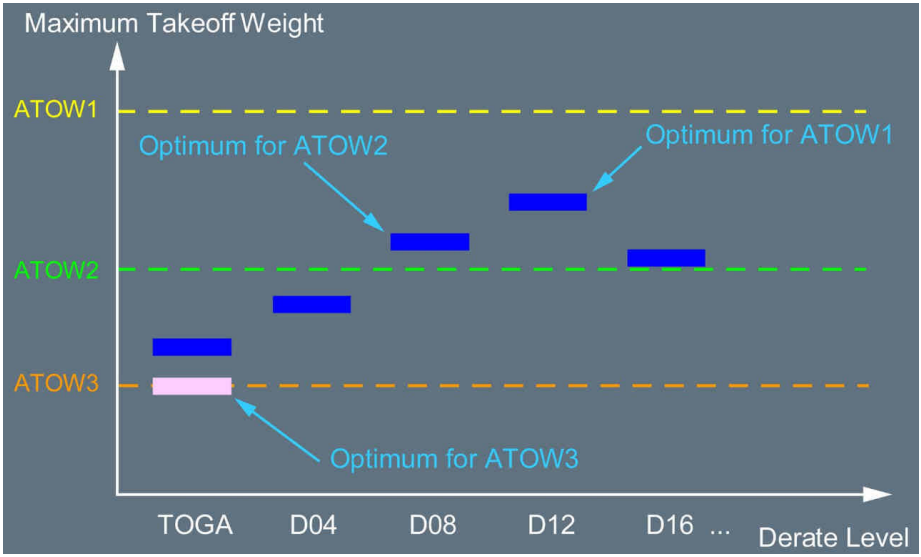
ATOW2 CASE

TOGA is the optimum derate level.

If FLEX Takeoff is permitted, the following two tables are displayed:
- The TOGA table displays the actual OAT and associated takeoff data
- The FLEX table displays for each permitted TFLEX the associated takeoff data.

WITH VMC LIMITATION

Optimum Derate With VMC Limitation



ATOW1 CASE

D12 is displayed as the optimum derate level, even if it is not possible to takeoff (MTOW(perf) lower than ATOW1).

ATOW2 CASE

D08 is displayed as the optimum derate level, even if it is allowed to takeoff with D12. However, it is not permitted to takeoff using D16 in this example, even if it is theoretically possible to takeoff with this derate level.

ATOW3 CASE

TOGA is the optimum derate level.

If FLEX Takeoff is permitted, the following two tables are displayed:
- The TOGA table displays the actual OAT and associated takeoff data
- The FLEX table displays for each permitted TFLEX the associated takeoff data.

However, it is allowed to takeoff with D04, D08 and D12 in this example.

It is still not permitted to takeoff using D16 in this example, even if it is theoretically possible to takeoff with this derate level.

STOP MARGIN

Applicable to: ALL

GENERAL

The stop margin is the difference between the Accelerate-Stop Distance (ASD) and the available runway length including the Stopway (SWY).

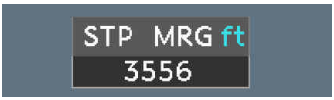
T.O PERF

The display of the stop margin depends on the V1 option:

WHEN FLEX TAKEOFF IS POSSIBLE

One Stop Margin

STP MRG



Only one stop margin is displayed, if V1 type is:
- A V1 min setting, or
- A V1 max setting.

Two Stop Margins

STP MRG

Two stop margins are displayed, if V1 type is:
- A V1 mean setting, or
- A range of V1 setting.

The first value corresponds to the maximum stop margin (i.e. the stop margin calculated for the lowest permitted V1).
The second value corresponds to the minimum stop margin (i.e. the stop margin calculated for the highest permitted V1).

WHEN FLEX TAKEOFF IS NOT POSSIBLE

STP MRG

STP MRG

Only one stop margin is displayed, if the V1 type is:
- A V1 min setting, or
- A V1 max setting.

STP MRG V1 Min & STP MRG V1 Max

STP MRG V1 Min & STP MRG V1 Max

Two stop margins are displayed, if the V1 type is:
- A V1 mean setting, or
- A range of V1 setting.

STP MRG V1 Min corresponds to the maximum stop margin (i.e. the stop margin calculated for the lowest permitted V1).
STP MRG V1 Max corresponds to the minimum stop margin (i.e. the stop margin calculated for the highest permitted V1).

TAKEOFF LIMITATION CODES

Applicable to: ALL

GENERAL

Several regulatory requirements limit takeoff performance. They are called takeoff limitations.

T.O PERF

The requirements that limit performance in specific cases are identified in the computation results via limitation codes.
Usually, MTOW(perf) is obtained at the intersection of two limitation curves. For this reason, the limitation codes are always indicated by two codes.
The two codes are identical if MTOW(perf) is only limited by one limitation.
The following table indicates the various codes that can appear:

TOW	Maximum computation weight, or maximum structural weight
RWY0	All-engine Takeoff Distance (TOD0)
	or All-engine Takeoff Run (TOR0)
	or All-engine Accelerate-Stop Distance (ASD0)
RWY1	One-engine Inoperative Takeoff Distance (TOD1)
	or One-engine Inoperative Takeoff Run (TOR1)
	or One-engine Inoperative Accelerate-Stop Distance (ASD1)
VMCG	V1 limited by Certified Minimum Control Speed on Ground
TIRE	Vlof limited by Maximum Tire Speed
BRK	V1 limited by Maximum Brake Energy
VMCA	V2 limited by certified Minimum Control Speed in the Air
1SEG	First Segment Climb Gradient
2SEG	Second Segment Climb Gradient
3SEG	Acceleration (third) Segment
FTO	Final Takeoff Climb Gradient
OBS	Obstacle Clearance
VMU	Minimum Unstick Speed

Customized codes may differ from the above listed.

AERODYNAMIC CONFIGURATION

Applicable to: ALL

GENERAL

For more information about aerodynamic configuration, *Refer to Aerodynamic Configuration (Input)* .

If the takeoff performance for two aerodynamic configurations is identical, the highest flap setting is recommended.

L2 The highest flap setting corresponds to the configuration that provides the lowest takeoff speeds and, therefore, improves safety during a rejected takeoff (RTO).

L1 T.O PERF

The FLAPS field on the RESULTS panel displays the selected or optimized configuration.

The optimization process keeps the configuration that provides the maximum performance limited takeoff weight (or the maximum TFLEX).

If the weight is the same for several configurations, the configuration that provides the lowest takeoff speeds is selected.

TAKEOFF SHIFT

Applicable to: ALL

GENERAL

The takeoff shift is a reduction of the takeoff distances (TORA, TODA, ASDA) due to a shifted entry of the aircraft on the runway.

T.O PERF

WHEN FLEX TAKEOFF IS POSSIBLE

If the runway length has been modified, the flight crew can access the takeoff shift via the selection of a TFLEX (or the OAT for TOGA) in the RESULTS tables.

WHEN FLEX TAKEOFF IS NOT POSSIBLE

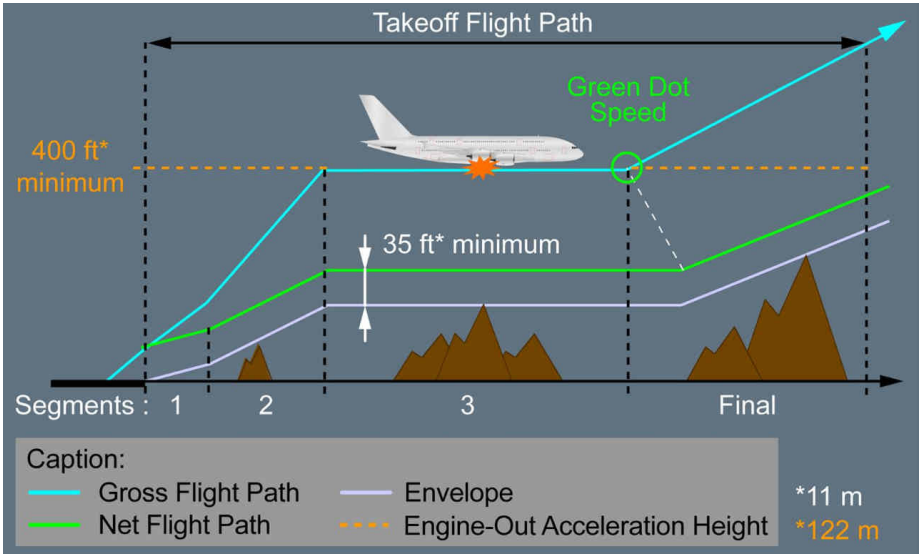
The RESULTS panel displays the takeoff shift (T.O SHIFT) of the SINGLE RWY COMPUTATION panel.

ENGINE-OUT ACCELERATION ALTITUDE

Applicable to: ALL

L2 GENERAL

Engine-Out Acceleration Height



The certified minimum acceleration height is 400 ft above the takeoff surface.
The gross minimum acceleration height ensures that the obstacles are cleared by the net takeoff flight path with the regulatory margin.
The maximum acceleration height ensures that acceleration to Green Dot speed and cleanup can be achieved within the maximum permitted 10 min of TOGA.

L1 T.O PERF

WHEN FLEX TAKEOFF IS POSSIBLE

The flight crew can access the computed engine-out acceleration altitude value via the selection of a TFLEX (or the OAT for TOGA) in the RESULTS tables.

WHEN FLEX TAKEOFF IS NOT POSSIBLE

The EO ACCEL field on the RESULTS panel displays the computed engine-out acceleration altitude value.

Note: *This value is a pressure altitude.*

MORE PANEL

Applicable to: ALL

The MORE panel displays the following information:

- The results of the T.O PERF computation, identical to the results displayed on the RESULTS panel
- The thrust reverser status for the T.O PERF computation:
  - For dry and wet runway conditions, the thrust reverser status is: NO REVERSE THRUST CREDIT
  - For contaminated runways, the thrust reverser status is defined as per Operator policy.
- Additional results data that the Operator can customize.

MORE Panel

XCHECK WITH AVIONICS

Applicable to: ALL

The XCHECK WITH AVNCS function enables the flight crew to crosscheck the FMS takeoff performance entries with the OIS takeoff performance results.

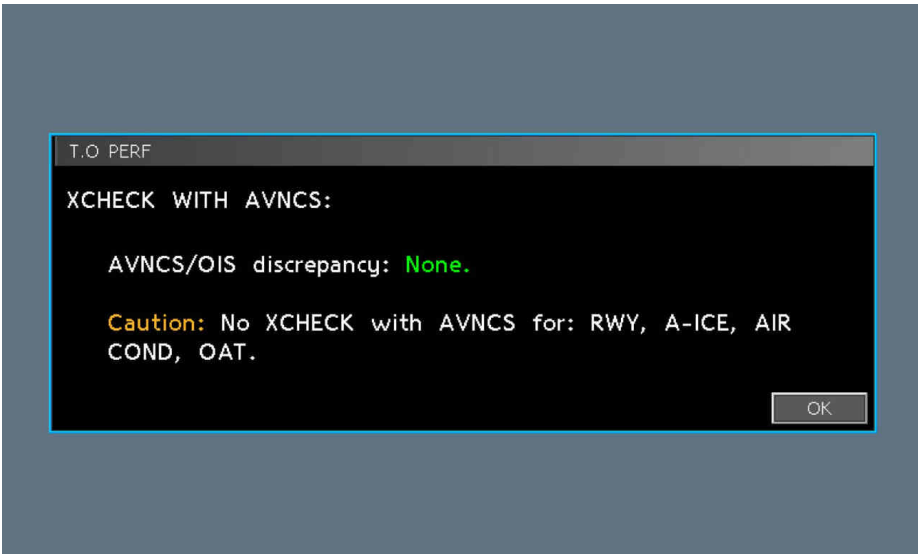
L2 For more information about the XCHECK WITH AVNCS procedure, *Refer to PRO-NOR-SOP-60-B FMS INITIALIZATION_FMS DATA CROSSCHECK* .

L1 The following takeoff performance data are crosschecked:

- Takeoff Speeds: V1, VR, V2
- Aerodynamic configuration (FLAPS)
- Takeoff weight (TOW)
- Flexible Temperature (TFLEX)
- QNH .

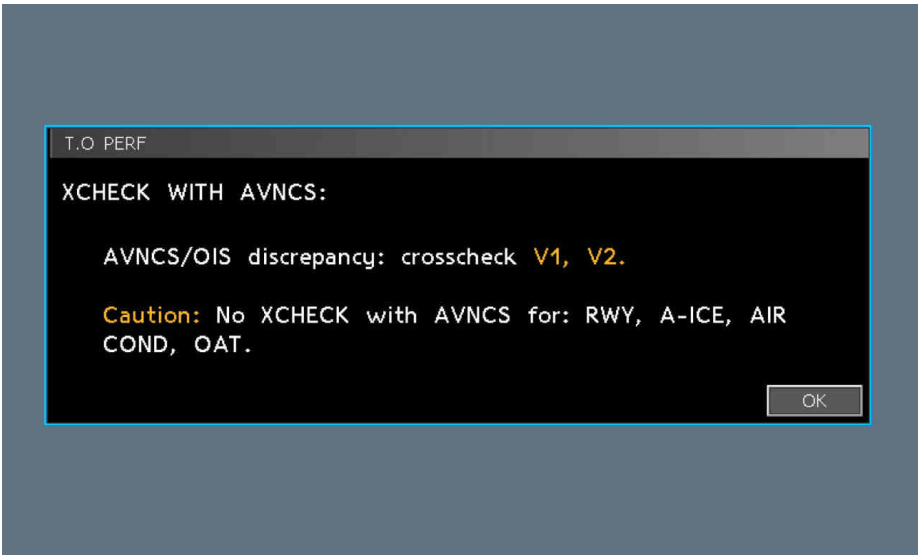
If there is no discrepancy between the FMS takeoff performance entries and the OIS takeoff performance results, T.O PERF displays the following popup message.

AVNCS/OIS: no Discrepancy



If there is one or more discrepancies between the FMS takeoff performance entries and the OIS takeoff performance results, T.O PERF displays the following popup message. The discrepancy parameters are displayed in amber (e.g. V1 and V2 in the following example).

AVNCS/OIS: Discrepancies



Note: *There is no crosscheck for the following parameters: RWY, A-Ice, AIR COND, OAT.*

WHEN FLEX TAKEOFF IS POSSIBLE

When the flight crew has performed a T.O PERF computation, and if a FLEX takeoff is possible, two tables are displayed on the RESULTS panel:

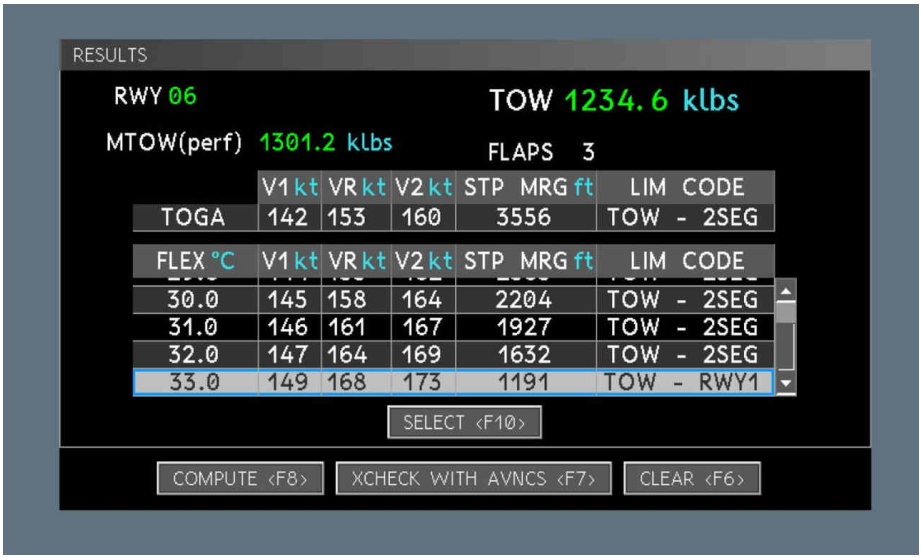
- A table showing performance results at TOGA thrust
- A table showing performance results for different possible TFLEX.

When the flight crew uses the XCHECK WITH AVNCS function, the crosscheck is performed with:

- The aerodynamic configuration and the TOW displayed on the RESULTS panel
- The QNH entered in the CONDITIONS panel
- The thrust and associated takeoff speeds of the selected line in the tables.

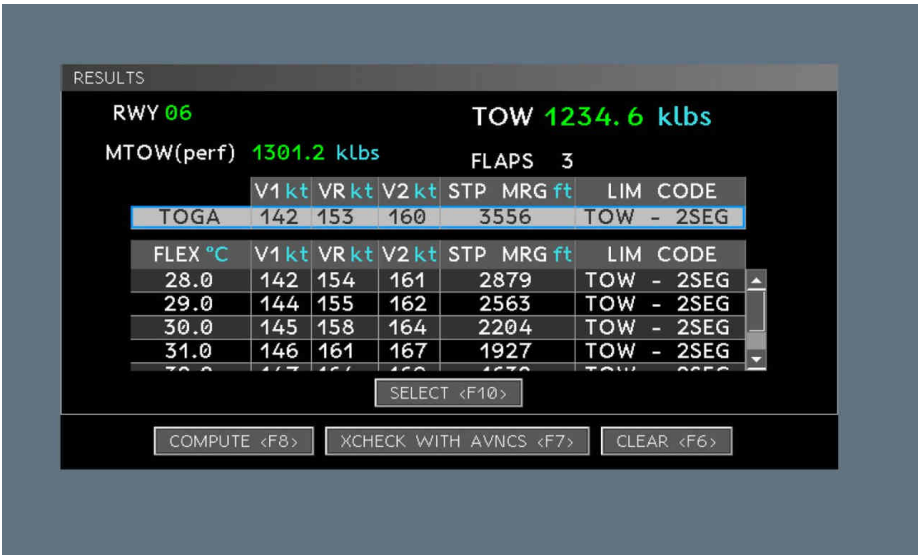
In the following example, if the flight crew uses the XCHECK WITH AVNCS function, the crosscheck will be performed with the "33.0" TFLEX line.

TFLEX Line Selected



In the following example, if the flight crew uses the XCHECK WITH AVNCS function, the crosscheck will be performed with the TOGA line.

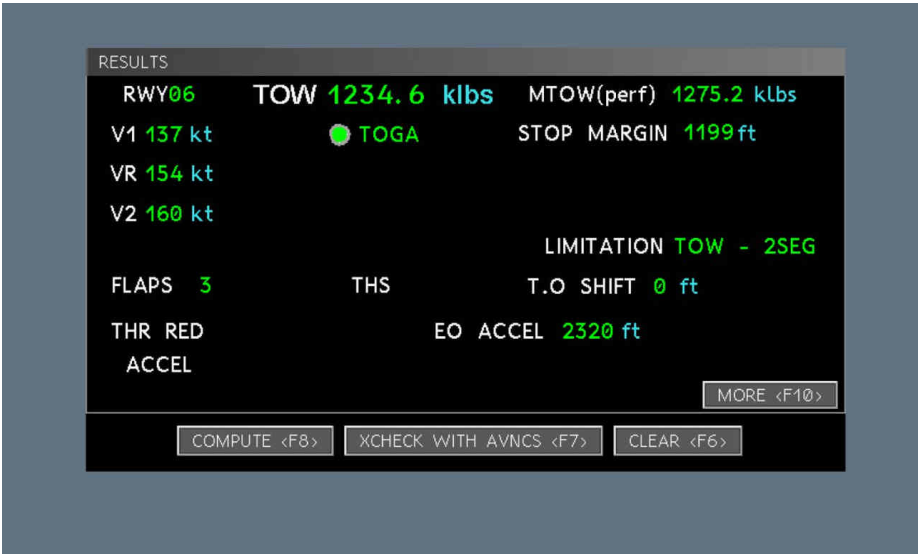
TOGA Line Selected



WHEN FLEX TAKEOFF IS NOT POSSIBLE

When the flight crew has performed a T.O PERF computation, if a FLEX takeoff is not possible, T.O PERF displays the results with the following layout.

RESULTS Panel



When the flight crew uses the XCHECK WITH AVNCS function, the crosscheck is performed with:

- The takeoff speeds, the aerodynamic configuration, the TOW, and TOGA (or Derate level) displayed on the RESULTS panel
- The QNH entered in the CONDITIONS panel.

XCHECK WITH AVNCS ASSUMPTIONS

TOW

The XCHECK WITH AVNCS function is active if and only if the calculated MTOW(perf) is equal to or above than the TOW value.
The XCHECK WITH AVNCS function compares the TOW value with the Gross Weight (GW) coming from the ECAM and displayed on the permanent data of the System Display (SD). Consequently, the TOW crosscheck does not make sense if it is performed before the end of the refueling.
The TOW crosscheck is successful if GW is included in the following weight range: 0.99*TOW ≤ GW ≤ 1.0035*TOW.

TAKEOFF SPEEDS

The VR/V2 crosscheck is successful if:
- The VR value inserted in the FMS T.O page is equal to the VR value calculated in T.O PERF
- The V2 value inserted in the FMS T.O page is equal to the V2 value calculated in T.O PERF.

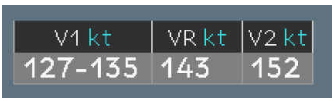
When FLEX Takeoff is Possible

Single V1

Single V1

V1 Range

V1 Range



When FLEX Takeoff is not possible

Single V1

Single V1

V1 Range

V1 Range

FLAPS

The FLAPS crosscheck is successful if the FLAPS selection on the FMS T.O page corresponds to the one selected or computed in T.O PERF.

QNH

The XCHECK WITH AVNCS function checks the QNH if and only if the barometric reference of the CM1 is QNH.
The QNH crosscheck is successful if the QNH displayed on the EFIS Control Panel of the CM1 (named CM1_QNH) is included in the following QNH range compared to the entered QNH in T.O PERF (named OIS_QNH): OIS_QNH - 0.99 hPa ≤ CM1_QNH ≤ OIS_QNH + 0.99 hPa.

XCHECK WITH AVNCS ASSUMPTIONS

THRUST

The Thrust crosscheck of the XCHECK WITH AVNCS function compares the Thrust selection of the FMS T.O page with the selected or calculated thrust in T.O PERF.
The Thrust crosscheck rules are expressed in the following matrix table:

XCHECK WITH AVNCS popup message		Thrust in FMS T.O page		
		TOGA	FLEX	DERATED
Thrust in T.O PERF results	TOGA	Caution: No XCHECK with AVNCS for: THRUST	AVNCS/OIS discrepancy: crosscheck THRUST	Caution: No XCHECK with AVNCS for: THRUST
	FLEX	AVNCS/OIS discrepancy: crosscheck THRUST	*Flexible Temperature comparison*	AVNCS/OIS discrepancy: crosscheck THRUST
	DERATED	Caution: No XCHECK with AVNCS for: THRUST	AVNCS/OIS discrepancy: crosscheck THRUST	Caution: No XCHECK with AVNCS for: THRUST

The FMS_FLEX vs. T.O PERF_FLEX check requires a flexible temperature comparison before displaying a XCHECK WITH AVNCS message.
In this case, the Thrust crosscheck of the XCHECK WITH AVNCS function compares the FLEX temperature value inserted in the FMS T.O page with the Flexible Temperature (TFLEX) value computed by T.O PERF.
This crosscheck is successful if the inserted FLEX temperature is included in the following temperature range: TFLEX - 5 °C ≤ FLEX ≤ TFLEX.
Otherwise, the XCHECK WITH AVNCS popup message displays "AVNCS/OIS discrepancy: crosscheck THRUST".

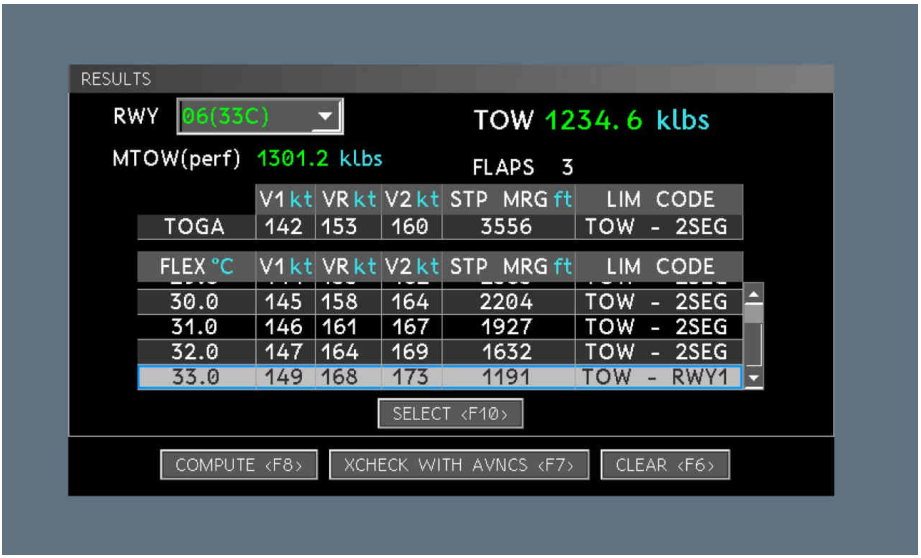
Intentionally left blank

COMPUTATION RESULTS

Applicable to: ALL

The flight crew can access the results for each runway via the RWY drop-down list.

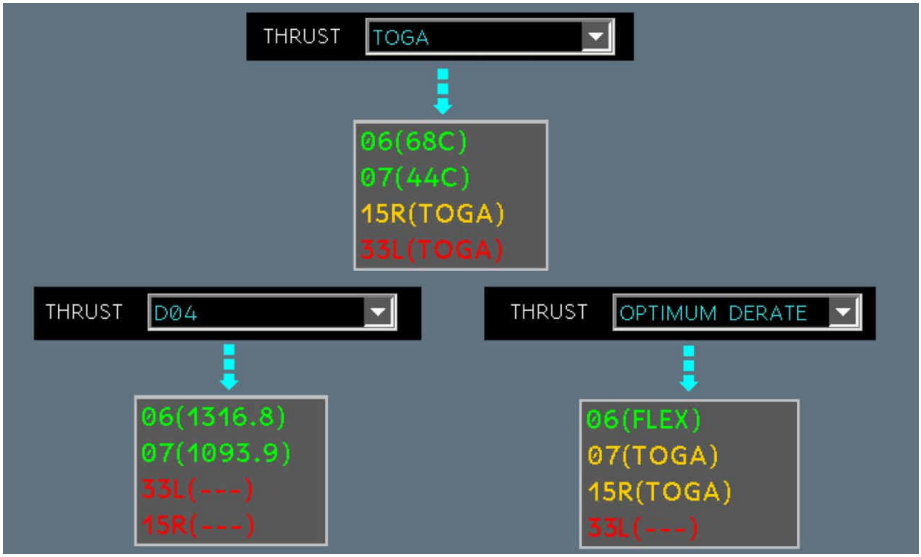
Multiple RESULTS Panel - MULTIPLE RWY COMPUTATION - One Step



MULTIPLE RWY COMPUTATION

Applicable to: ALL

Runway Selection



TOGA

For each runway, TFLEX (or TOGA when FLEX Takeoff is not permitted) is displayed between brackets after the Runway ID.
The list is sorted by temperature, then by weight (both in decreasing order). Moreover, it is color-coded.

GREEN

Indicates that the results correspond to a FLEX Takeoff.

AMBER

Indicates that the results correspond to a takeoff at TOGA, when MTOW(perf) is above, or equal to, TOW.

RED

Indicates that the results correspond to a takeoff at TOGA, when MTOW(perf) is below TOW.

DERATE

For each runway, the maximum performance limited takeoff weight is displayed between brackets after the Runway ID.
The list is sorted by weight from the highest to the lowest and is color-coded.

GREEN

When MTOW(perf) is above, or equal to, TOW.

RED

When MTOW(perf) is below TOW.

OPTIMUM DERATE

For each runway, FLEX (or TOGA, or the derate level) is displayed between brackets after the Runway ID.
The list is sorted by temperature, then by weight (both in decreasing order). Moreover, it is color-coded.

GREEN

Indicates that the results correspond to FLEX Takeoff.

AMBER

Indicates that the results correspond to a takeoff at TOGA (or derate level), when MTOW(perf) is above, or equal to, TOW.

RED

Indicates that the results correspond to a takeoff at TOGA (or derate level), when MTOW(perf) is below TOW.

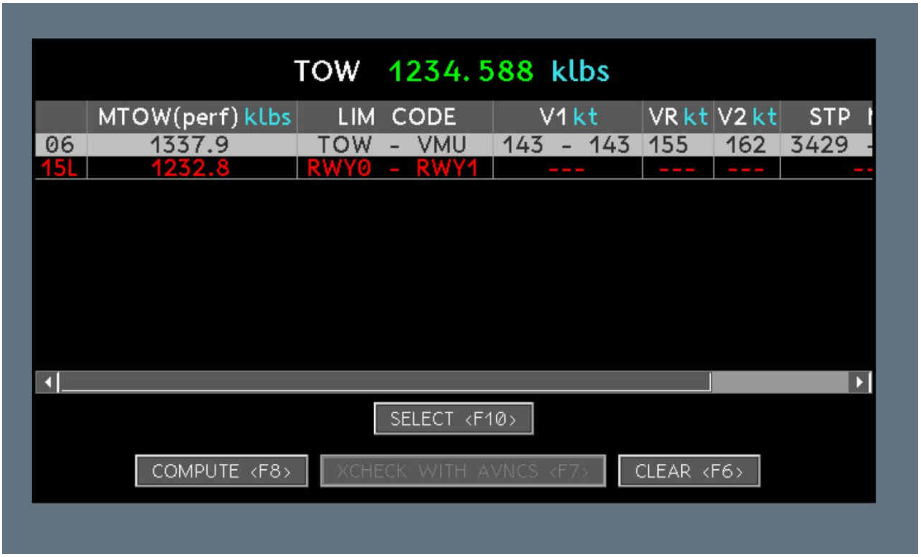
Intentionally left blank

COMPUTATION RESULTS - FIRST STEP

Applicable to: ALL

For each runway selecte within the MULTIPLE RWY COMPUTATION panel, the first step calculation displays the results at TOGA (or Derate level).

Multiple RESULTS Panel - MULTIPLE RWY COMPUTATION - First Step



When the aircraft cannot take off at the actual takeoff weight for a given runway (MTOW(perf) below the TOW value entered by the flight crew), the red labels "- - -" are displayed instead of the output values, and it is not possible to perform the second step calculation.

XCHECK WITH AVIONICS

The XCHECK WITH AVNCS function enables the flight crew to crosscheck the FMS takeoff performance entries with the OIS takeoff performance results.

L2 For more information about the XCHECK WITH AVNCS procedure, *Refer to PRO-NOR-SOP-60-B FMS INITIALIZATION_FMS DATA CROSSCHECK* .

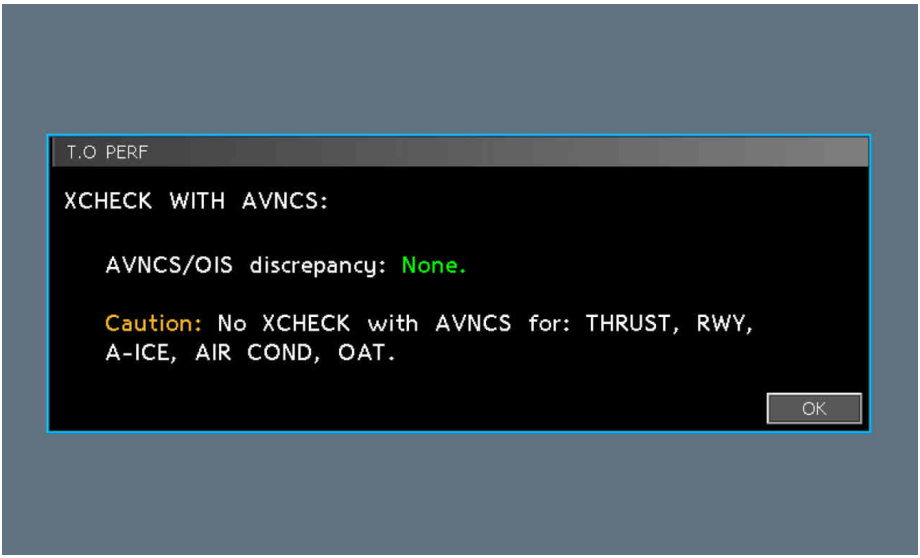
L1 When the flight crew uses the XCHECK WITH AVNCS function, the crosscheck is performed with the takeoff performance data of the line that the flight crew has selected in the table displayed on the RESULTS panel.

The following takeoff performance data are crosschecked:

- Takeoff Speeds: V1, VR, V2
- Aerodynamic configuration (FLAPS)
- Takeoff weight (TOW)
- Flexible Temperature (TFLEX)
- QNH .

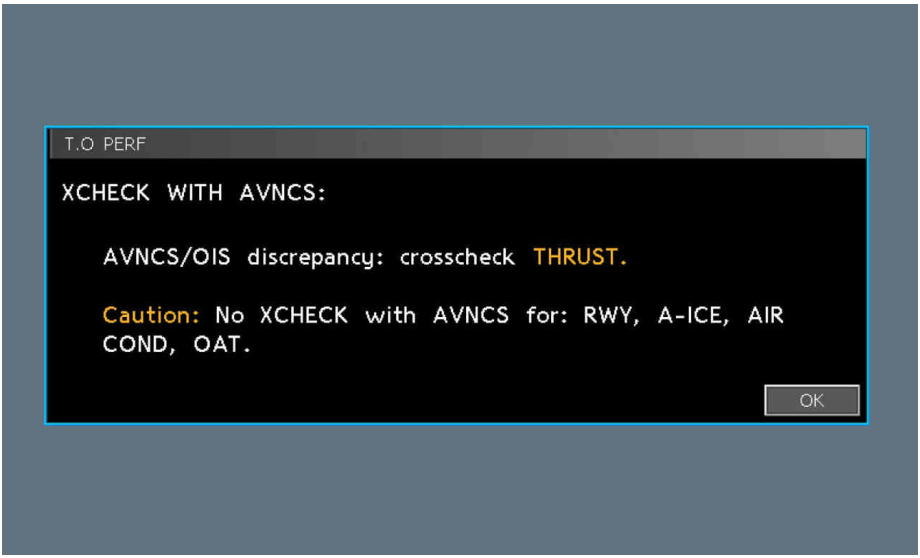
If there is no discrepancy between the FMS takeoff performance entries and the OIS takeoff performance results, T.O PERF displays the following popup message.

AVNCS/OIS: no Discrepancy



If there is one or more discrepancies between the FMS takeoff performance entries and the OIS takeoff performance results, T.O PERF displays the following popup message. The discrepancy parameters are displayed in amber (e.g. THRUST in the following example).

AVNCS/OIS: Discrepancies



Note: There is no crosscheck for the following parameters: RWY, A-Ice, AIR COND, OAT.

GREY LINE SELECTED ON THE RESULTS TABLE

When the flight crew uses the XCHECK WITH AVNCS function, the crosscheck is performed with:

- The TOW displayed on the RESULTS panel
- The QNH entered in the CONDITIONS panel
- TOGA (or Derate level) and associated takeoff speeds of the selected line in the tables.

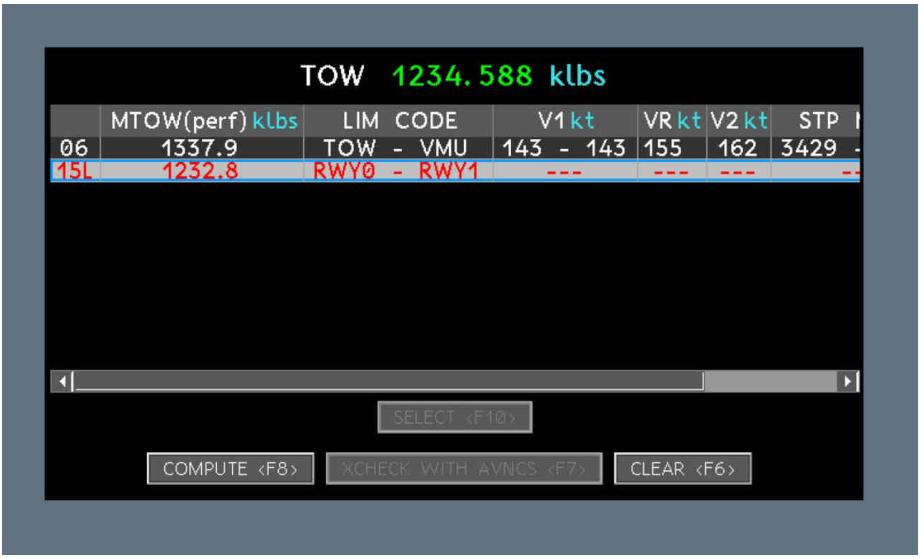
In the following example, if the flight crew uses the XCHECK WITH AVNCS function, the crosscheck will be performed with the 06 RWY ID line.

Grey Line Selected

RED LINE SELECTED ON THE RESULTS TABLE

The aircraft cannot take off at the actual takeoff weight for the selected runway
Therefore, the XCHECK WITH AVNCS button is disabled: The crosscheck function is inactive.

Red Line Selected



SPECIFIC XCHECK WITH AVNCS RULE ON THRUST

L2 For more information about the XCHECK WITH AVNCS assumptions, *Refer to PER-TOF-TOR-MRS-XAVN XCHECK with Avionics Assumptions* .

L1 The Thrust crosscheck of the XCHECK WITH AVNCS function compares the Thrust selection of the FMS T.O page with the selected or calculated thrust in T.O PERF.
At this first step of the calculation process, T.O PERF displays the results at TOGA (or Derate level).
The Thrust crosscheck rules are expressed in the following matrix table:

XCHECK WITH AVNCS popup message		Thrust in FMS T.O page		
		TOGA	FLEX	DERATED
Thrust in T.O PERF results	TOGA	Caution: No XCHECK with AVNCS for: THRUST	AVNCS/OIS discrepancy: crosscheck THRUST	Caution: No XCHECK with AVNCS for: THRUST
	DERATED	Caution: No XCHECK with AVNCS for: THRUST	AVNCS/OIS discrepancy: crosscheck THRUST	Caution: No XCHECK with AVNCS for: THRUST

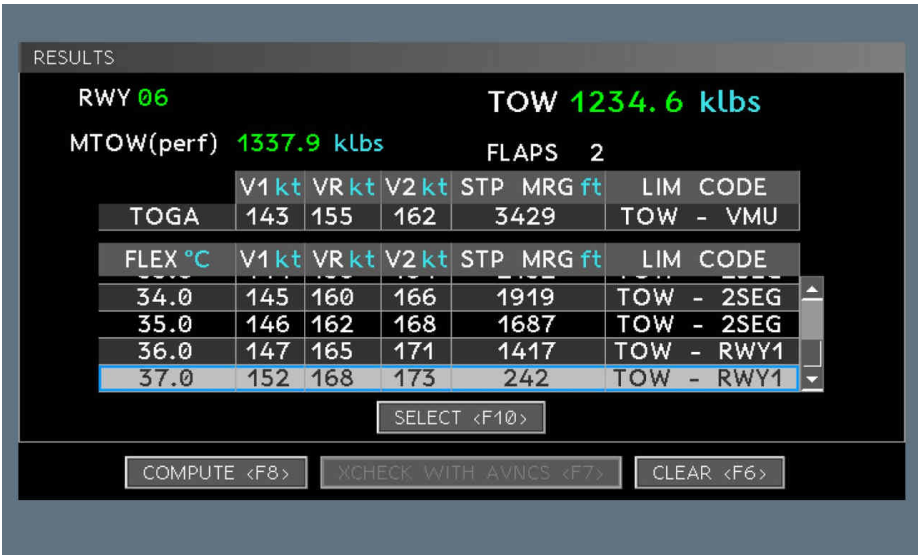
If the thrust selected in the FMS T.O page is TOGA or DERATED, then no crosscheck is performed with the thrust value computed by the OIS . The XCHECK WITH AVNCS popup message displays " Caution: No XCHECK with AVNCS for: THRUST".
If a FLEX temperature value is inserted in the FMS T.O page, then the XCHECK WITH AVNCS popup message displays "AVNCS/OIS discrepancy: crosscheck THRUST ".

COMPUTATION RESULTS - SECOND STEP

Applicable to: ALL

As soon as the flight crew has selected a runway via the SELECT button on the first step RESULTS panel, a computation is launched to obtain a results table of takeoff data.

Multiple RESULTS Panel - MULTIPLE RWY COMPUTATION - Second Step



Intentionally left blank

DEFINITION OF TOGA THRUST

Applicable to: ALL

TOGA is the maximum thrust certified for takeoff.
When all engines are operative, the TOGA thrust rating must not be used for more than 5 minutes.
In the case of one engine out, the TOGA thrust rating may be used for up to 10 minutes.

The flight crew must use TOGA thrust for takeoff, if at least one of the following conditions applies:
- Maximum power is required
- Performance reasons
- FLEX Takeoff not permitted.

RECOMMENDATIONS

Applicable to: ALL

When windshear is expected along takeoff path, the use of TOGA thrust is recommended.
This maintains acceleration capability.

Intentionally left blank

DEFINITION OF FLEX TAKEOFF

Applicable to: ALL

When the actual takeoff weight is lower than the maximum performance limited takeoff weight, the aircraft may comply with the regulatory requirements with a reduced thrust, called Flexible Takeoff Thrust.

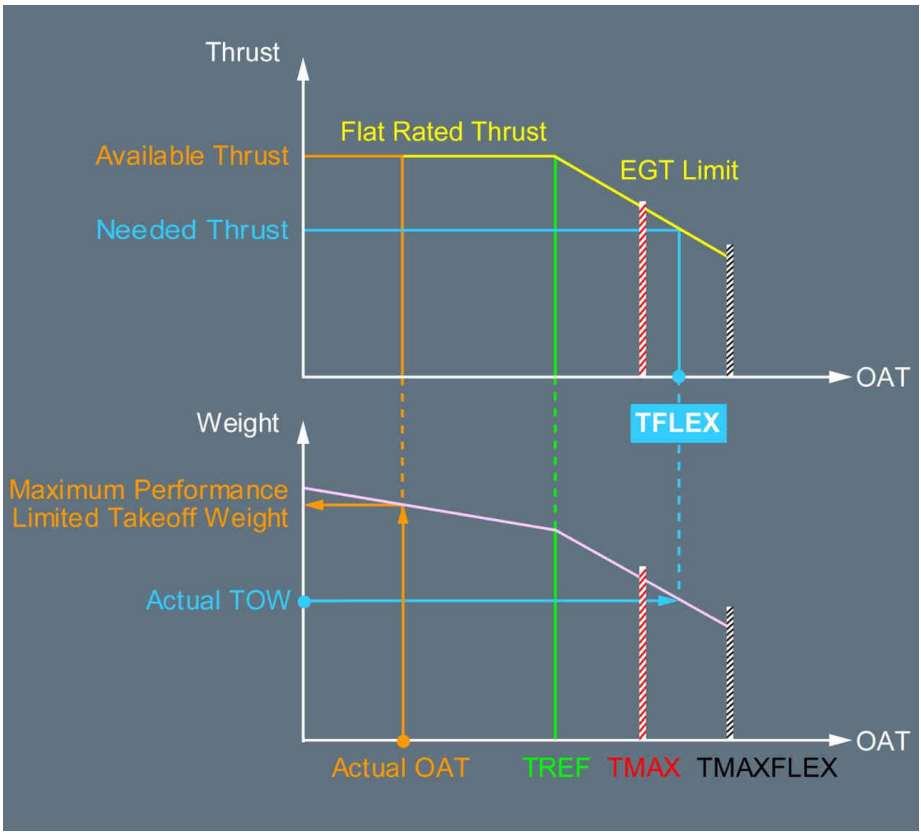
This takeoff operation is called FLEX Takeoff.

PRINCIPLE

Applicable to: ALL

The FLEX Takeoff principle is based on the change in maximum available takeoff thrust with OAT. The maximum performance limited takeoff weight depends on the maximum available takeoff thrust, therefore it is possible to determine a temperature at which the actual takeoff weight would be limited by performance.
This temperature is referred to as TFLEX (Flexible Temperature).

FLEX Takeoff Principle



ADVANTAGES

Applicable to: ALL

The use of FLEX Takeoff extends engine life and reliability, as well as reduces maintenance and operating costs.
The effect is particularly significant with the first degrees of TFLEX.

REQUIREMENTS

Applicable to: ALL

FLEX Takeoff is not permitted on contaminated runways.
For more information about contaminated runways, *Refer to Runway Contamination* .

L2 Operators should check the maximum thrust (TOGA) by:

- Performing full-rated takeoffs at regular intervals, in order to detect a reduced EGT margin, or
- Maintaining an adequate engine monitoring program, in order to follow-up on the engine parameters.

RECOMMENDATIONS

Applicable to: ALL

The highest TFLEX extends engine life and save maintenance costs. However, if a high TFLEX is reduced by a few degrees only, the engines are not significantly affected.
The highest TFLEX will usually be obtained at the lowest flap setting. However, a higher flap setting provides a lower decision speed (V1) and more comfort.
To extend engine life and to save maintenance costs, the use of flap setting that provides the highest TFLEX is recommended. However, when the difference (in terms of TFLEX) between 2 configurations is low, the highest of both takeoff configurations is preferable.

TFLEX POSSIBLE RANGE

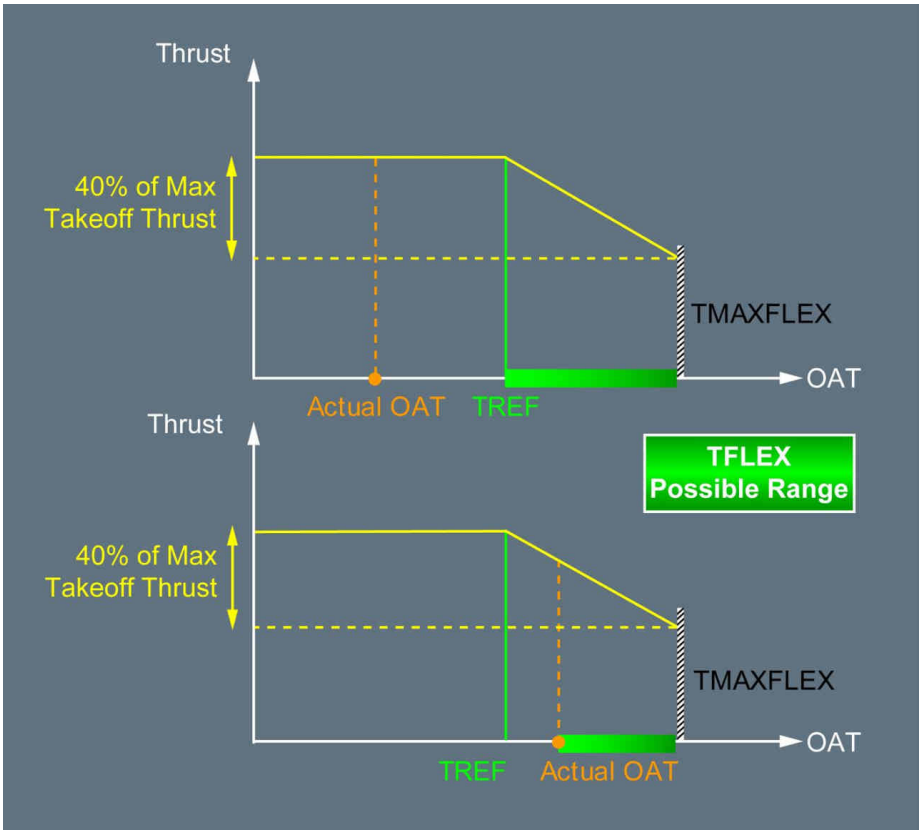
Applicable to: ALL

TFLEX cannot be:

- Higher than TMAXFLEX, equal to ISA + 60 (75 °C at sea level). The takeoff thrust cannot be reduced by more than 40 % from the full rated takeoff thrust.
- Lower than the Flat Rating Temperature (TREF), equal to ISA + 15 (30 °C at sea level).
- Lower than the actual OAT.

T.O PERF automatically takes into account the conditions listed above.

TFLEX Possible Range

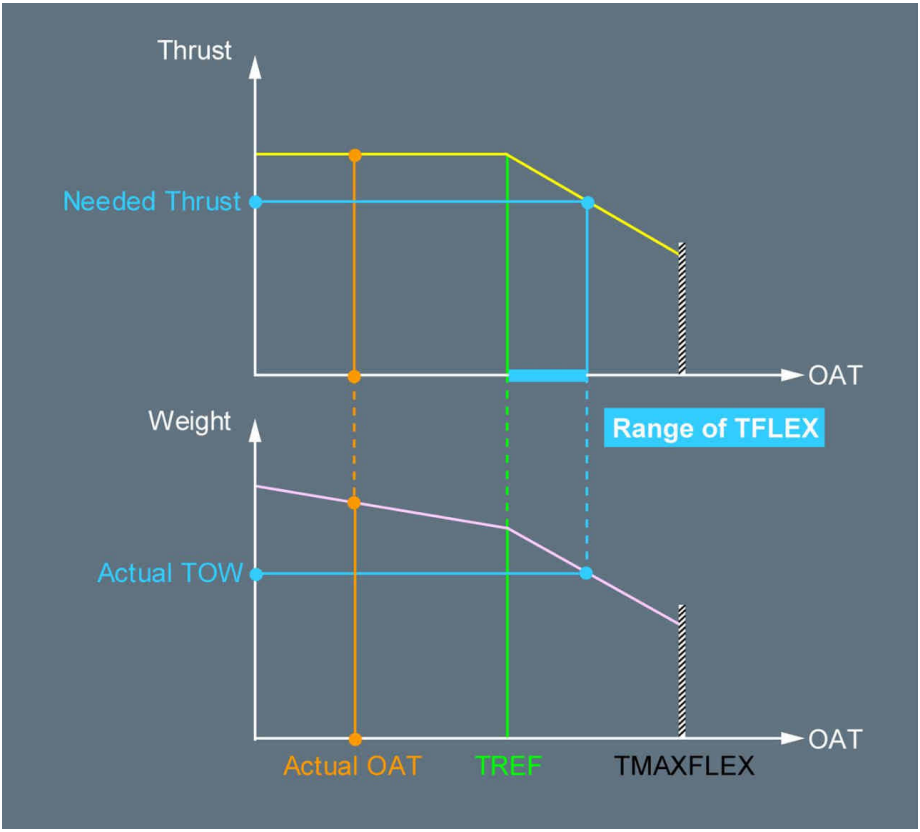


RANGE OF TFLEX

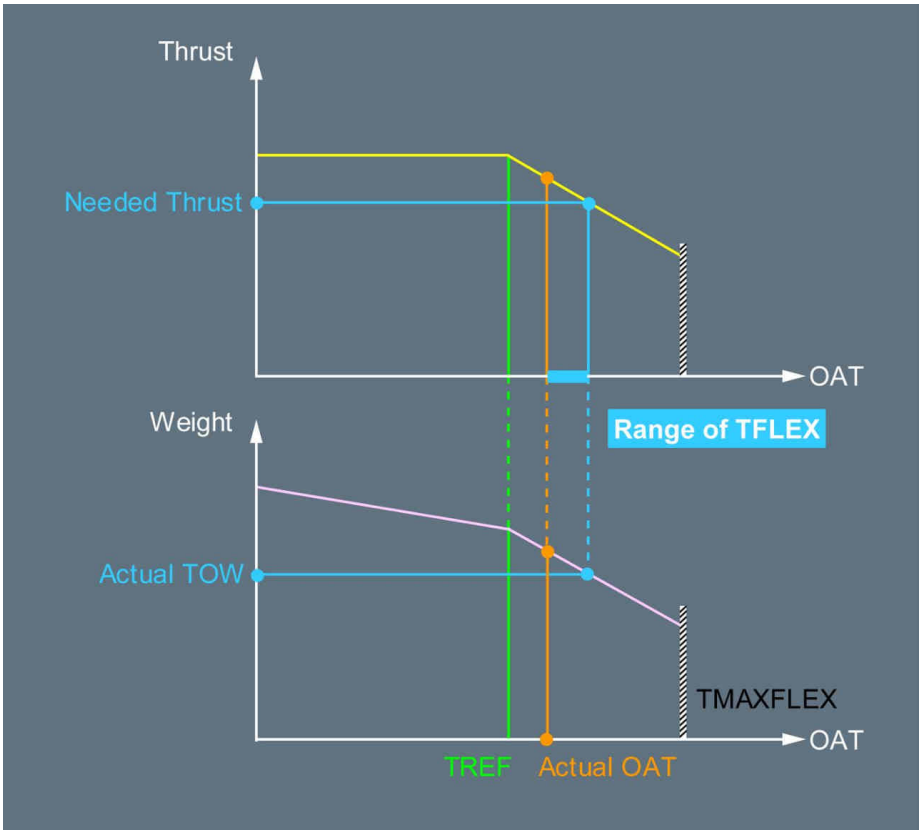
Applicable to: ALL

When a FLEX takeoff is permitted, the optimization provides results for a range of TFLEX. Therefore, it is possible to use a temperature that is lower than the maximum possible TFLEX calculated, in order to increase the performance margin.
This usually results in lower takeoff speeds (V1/VR/V2).

Range of TFLEX - Case 1



Range of TFLEX - Case 2

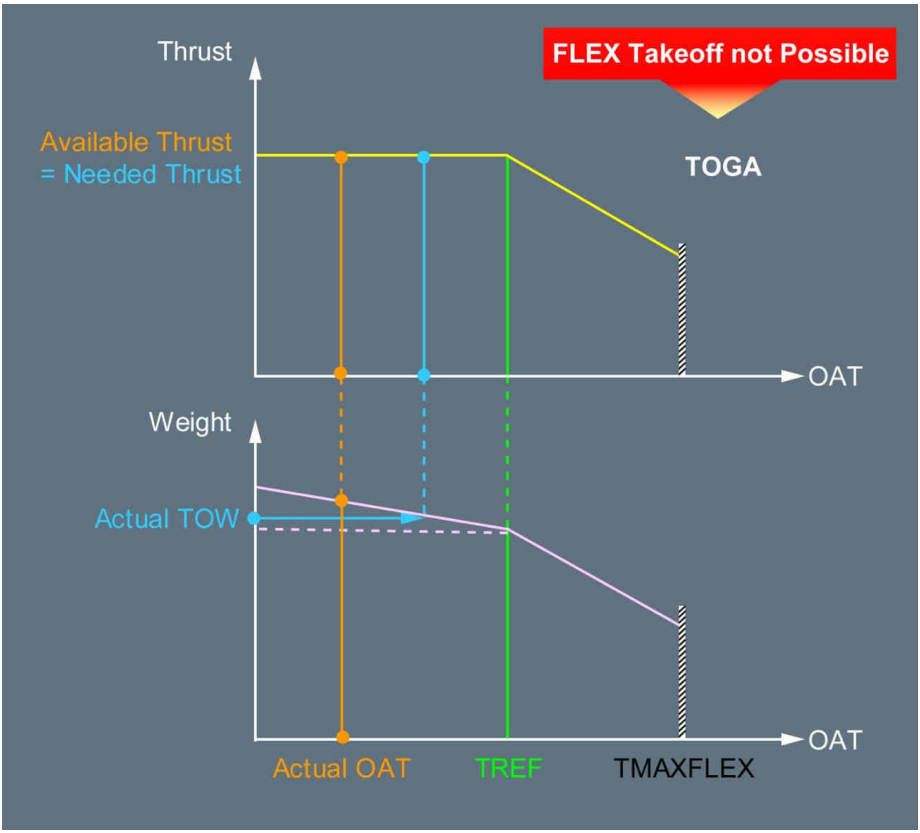


TFLEX LOWER THAN TREF

Applicable to: ALL

In some cases, even if the actual takeoff weight is lower than the maximum performance limited takeoff weight, it is not permitted to perform a FLEX Takeoff, because TFLEX is lower than TREF .
For more information about the TFLEX possible range, *Refer to PER-TOF-THR-FLX TFLEX Possible Range* .
In the above-mentioned cases, it is mandatory to use TOGA thrust. Takeoff speeds are optimized accordingly.
T.O PERF only displays a TOGA thrust result.

TFLEX lower than TREF



Intentionally left blank

DEFINITION OF DERATED TAKEOFF

Applicable to: ALL

A Derated Takeoff is defined as the takeoff operation at a thrust setting lower than TOGA, for which the AFM provides a set of takeoff limitations and performance data.
The AFM provides the THR values that correspond to each certified derated takeoff thrust setting. These THR values are considered as normal takeoff limits.

There are six derate levels:
- D04 corresponds to approximately a 4 % decrease in the maximum takeoff thrust
- D08 corresponds to approximately a 8 % decrease in the maximum takeoff thrust
- D12 corresponds to approximately a 12 % decrease in the maximum takeoff thrust
- D16 corresponds to approximately a 16 % decrease in the maximum takeoff thrust
- D20 corresponds to approximately a 20 % decrease in the maximum takeoff thrust
- D24 corresponds to approximately a 24 % decrease in the maximum takeoff thrust.

ADVANTAGE - IMPROVEMENT OF TAKEOFF PERFORMANCE

Applicable to: ALL

The advantage of a Derated Takeoff is to benefit from the increase in takeoff performance when the takeoff weight is limited by VMCG, due to the decrease in VMCG that is associated with the lower rating.

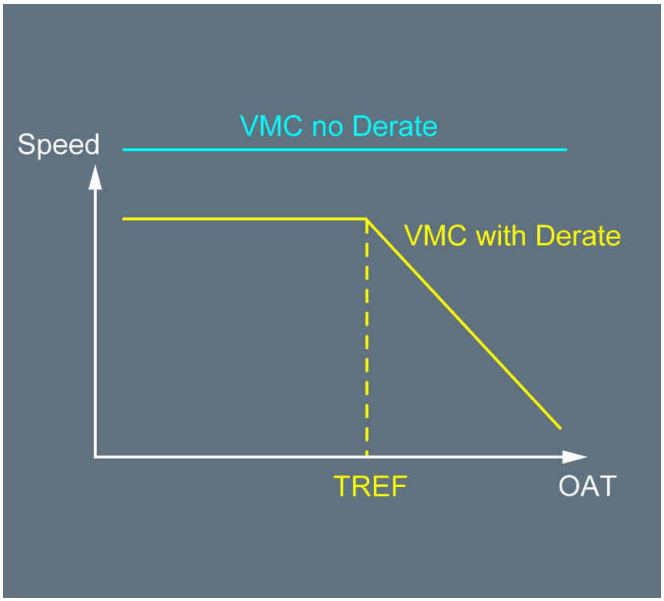
VMC DECREASE

Applicable to: ALL

L2 In the case of Derated Takeoff, the minimum control speeds (VMCG and VMCA) are decreased because:

- The derated thrust is lower than the maximum takeoff thrust
- The effect of temperature on maximum available thrust is taken into account, which is not the case for a FLEX Takeoff, since TOGA thrust may not be recovered during a Derated Takeoff.

VMC Decrease with Derate



VMCG LIMITING

VMCG only has an impact on the accelerate-stop distance, that includes an acceleration and a deceleration phase.
The decrease in VMCG allows to use lower V1 values in the speed optimization, which shortens both the acceleration and the deceleration distances, therefore largely compensating for the thrust loss.
If takeoff performance is limited by the VMCG limited weight, an overall improvement can be achieved by derating.

VMCA LIMITING

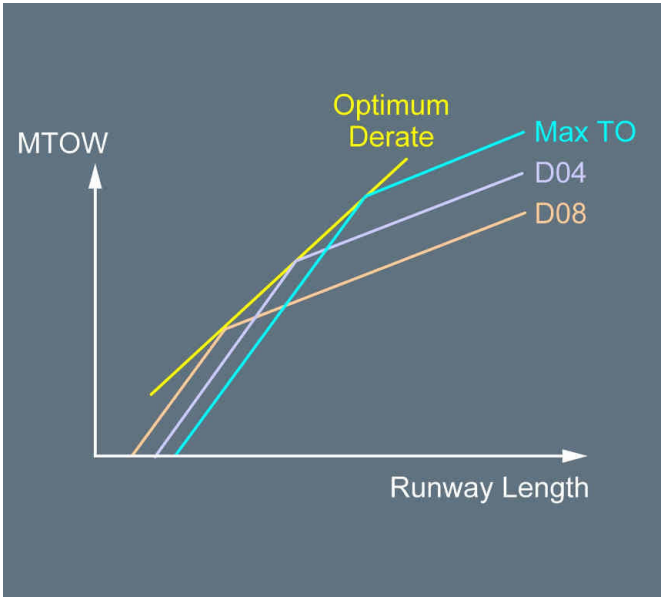
The penalizing effect on climb gradient of the decrease in thrust outweighs the advantage of a lower VMCA.
Therefore, Derated Takeoff would not improve the takeoff weight if VMCA limited.

OPTIMUM DERATE

Applicable to: ALL

When MTOW(perf) is VMCG limited, an optimum derate can be determined, as illustrated below:

MTOW(perf) vs. Runway Length



REQUIREMENTS

Applicable to: ALL

It is not permitted to combine a Derated Takeoff and a FLEX Takeoff.

L2 The flight crew selects the derate level on the MFD PERF TO page. This prevents the simultaneous selection of both a derate level and a TFLEX .

L1 When a Derated Takeoff is performed, the selection of full takeoff thrust by setting thrust levers to TOGA is not permitted below the speeds specified in the “Engine Failure After V1 - Continued Takeoff” Operating Technique, with the only exception of the Recovery Technique at Takeoff after penetrating unforecast windshear.

L2 For more information on the specified speeds, *Refer to PRO-ABN-NECA-10-GENGF Engine Failure after V1 - Proc* .

L1 Derated Takeoff is permitted on dry, wet and contaminated runways.

Derated Takeoff procedures do not permit the selection of TOGA in an emergency. Therefore FLEX Takeoff is expected to provide the best performance margin in most cases, with Derated Takeoff only to be used on limiting runways.

CAUTION	The use of derate levels lower than the one leading to the highest possible maximum performance limited takeoff weight is not permitted.

Note: *A lower derate level is a derate level that results in a higher thrust reduction.*

DEFINITIONS

Applicable to: ALL

Takeoff performance is impacted by runway contamination.

CONTAMINANTS

Contaminants can be classified into Fluid and Hard Contaminants:

FLUID CONTAMINANTS

WATER	Wet	Depth of water less or equal to 0.12 in.
	Standing Water	Due to heavy rainfall, and/or insufficient runway drainage. Deeper than 0.12 in.
SLUSH	Water saturated with snow that spatters when stepping firmly on it. Slush occurs at an approximate temperature of 5 °C, and an approximate density of 0.85 kg/l (7.1 lb/US Gal).	
WET SNOW	If compacted by hand, the snow will stick together, and usually forms a snowball. Its density is approximately 0.4 kg/l (3.35 lb/US Gal).	
DRY SNOW	Can be blown if loose, or if compacted by hand, will fall apart again upon release. Its density is approximately 0.2 kg/l (1.7 lb/US Gal).	

HARD CONTAMINANTS

COMPACTED SNOW	Snow that has been compressed (the usual friction coefficient is 0.2).
ICE	In icy conditions, the friction coefficient is 0.05 or below.

STATE OF RUNWAY

The contaminant characteristics (type, depth, appearance) determine the state of the runway.

DRY	A runway is dry when its surface is not: - Damp - Wet - Contaminated.
DAMP	A runway is damp: - When its surface is not dry - But when the water on it does not give it a shiny appearance.
WET	A runway is considered as wet: - When its surface has a shiny appearance - Due to a thin layer of Fluid Contaminant - With no substantial risk of hydroplaning. For Water, this layer may not exceed 0.12 in depth.
CONTAMINATED	A runway is contaminated when more than 25 % of its surface is covered with: - A layer of Fluid Contaminant that is not considered as thin

Continued on the following page

Continued from the previous page

	- A Hard Contaminant.

EFFECT ON PERFORMANCE

Applicable to: ALL

Contaminants are classified by their effect on aircraft performance.

FLUID CONTAMINANTS

Fluid Contaminants reduce friction forces, and cause:
- Precipitation drag
- Hydroplaning.

PRECIPITATION DRAG

L2 Precipitation drag includes:
- Displacement drag, that is produced by the displacement of the contaminant fluid from the path of the tire
- Spray impingement drag, that is produced by the spray thrown up by the wheels (mainly those of the Nose Landing Gear (NLG)) onto the fuselage.

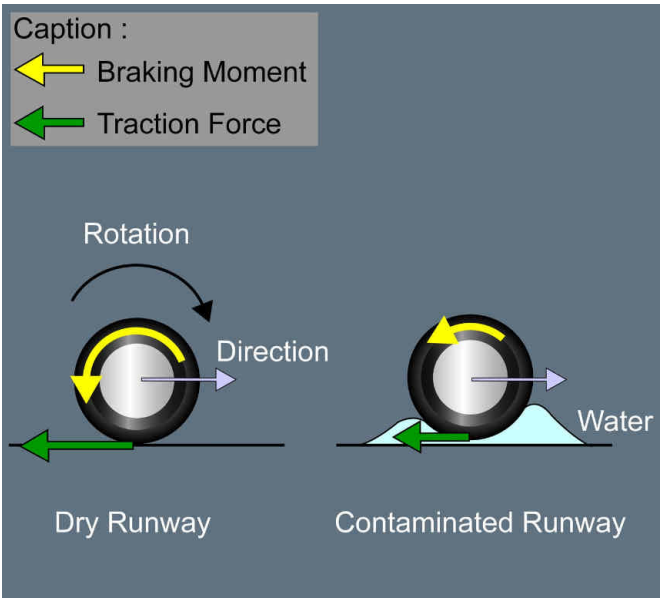
L1 Precipitation drag:
- Improves the deceleration rate, this has a positive effect in the case of a rejected takeoff
- Reduces the acceleration rate, this has a negative effect during takeoff.

The detrimental effect on the acceleration rate during takeoff requires that the depth of a Fluid Contaminant be no more than a maximum value (depending on the type of contaminant).

HYDROPLANING

L2 If there is water on the runway, a water film is created between the tire and the runway, that causes a reduction in the dry contact surface area between the tire and the runway.
This phenomenon becomes more critical at high speeds, when the rolling tire cannot evacuate the water fast enough.
Hydroplaning is a situation where the tires of the aircraft are, to a large extent, separated from the runway surface while floating on a thin film of fluid.
During hydroplaning, tire traction decreases to almost negligible values, thus rendering wheel braking and steering virtually ineffective.

Hydroplaning Phenomenon



Hydroplaning speed depends on tire pressure, and on the specific gravity of the contaminant (i.e. how dense the contaminant is).

L1 The hydroplaning speed is a threshold above which friction forces are severely reduced. Performance calculations on contaminated runways take into account the penalizing effect of hydroplaning.

HARD CONTAMINANTS

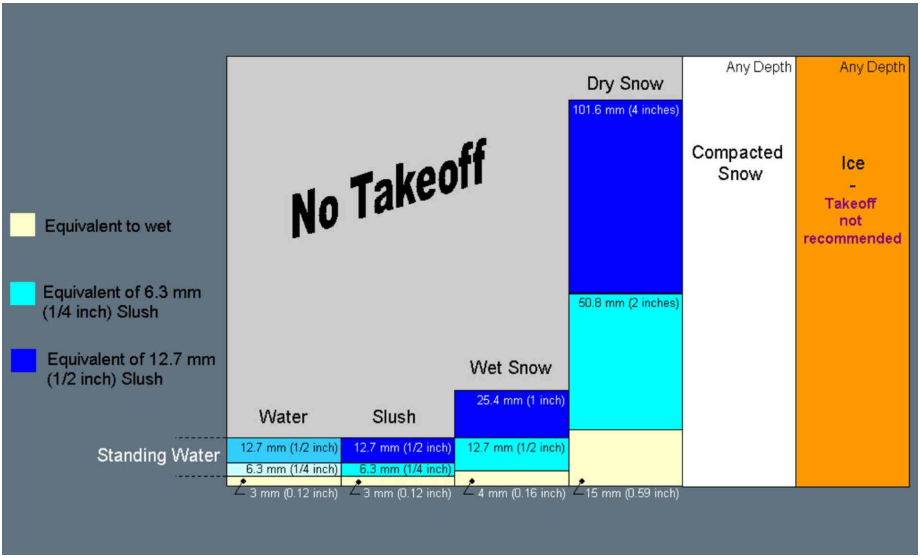
Hard Contaminants only reduce friction forces.

L2 The tires roll on top of a flat layer of Hard Contaminant. Therefore, only the friction coefficient (effective μ) is reduced, the depth of contaminant has no influence on takeoff performance.

EQUIVALENCES FOR PERFORMANCE

Applicable to: ALL

Runway Conditions



Takeoff performance is established only for some well-identified certified runway conditions. Within limits, it is possible to take into account other runway condition that may be encountered in operation, by using one of the identified states that has an equivalent impact on performance.

WET RUNWAY

In terms of performance, a Fluid Contamination is equivalent to wet, up to a maximum depth of:

- 3 mm (0.12 in) Water,
- 3 mm (0.12 in) Slush,
- 4 mm (0.16 in) Wet Snow,
- 15 mm (0.59 in) Dry Snow.

For more information on wet runway, *Refer to PER-TOF-CTA Definitions* .

CONTAMINATED RUNWAY

In terms of performance, an equivalence between Dry and Wet Snow and the certified contaminated runway conditions is defined.

EQUIVALENTS OF 6.3 MM (1/4 IN) SLUSH

- 12.7 mm (1/2 in) Wet Snow is equivalent to 6.3 mm (1/4 in) Slush,
- 50.8 mm (2 in) Dry Snow is equivalent to 6.3 mm (1/4 in) Slush.

EQUIVALENTS OF 12.7 MM (1/2 IN) SLUSH

- 25.4 mm (1 in) Wet Snow is equivalent to 12.7 mm (1/2 in) Slush,
- 101.6 mm (4 in) Dry Snow is equivalent to 12.7 mm (1/2 in) Slush.

For more information on contaminated runway, *Refer to PER-TOF-CTA Definitions* .

EFFECTIVE AND REPORTED FRICTION COEFFICIENTS

Applicable to: ALL

Airport authorities publish runway contamination data in a document called “SNOWTAM”, that includes:

- The type of contaminant
- The average depth for each third of total runway length
- The reported friction coefficient, or braking action.

The reported Friction coefficient (μ) is measured by friction-measurement vehicles, usually at comparatively low speed. However, the friction forces that are applicable to an aircraft (interaction tire/runway) depend on its weight, tire wear, tire pressure, anti-skid system efficiency and ground speed.
No universal correlation has been identified between the figures obtained from these measurement vehicles (reported μ), and the actual braking performance of an aircraft (effective μ).
In the case of runway contamination, the performance data is calculated for several well-identified types and depths of contaminant, and not as a function of the aircraft’s effective μ, except if the operator experience has permitted to establish such a correlation.

COMPUTATION ASSUMPTIONS

Applicable to: ALL

In the case of runway contamination, takeoff performance calculations are based on the following assumptions:

- The contaminant covers the entire length of the runway in a layer that has a uniform depth and density
- The friction coefficient is based on studies, and verified by tests
- The screen height at the end of the takeoff segment is 15 ft, instead of 35 ft.

In addition, for contaminated runways only:

- Drag increases, due to rolling resistance of the wheels
- Drag increases, due to the spray from the Nose Landing Gear (NLG) on the airframe and on the main gears
- Reverse thrust is used for deceleration
- Maximum thrust available is used for takeoff.

RESTRICTIONS

Applicable to: ALL

The following restrictions apply for operations on contaminated runways:

- FLEX takeoff is not permitted
- It is not recommended to take off from a runway that is covered with more than 25.4 mm (1 in) of Wet Snow or 101.6 mm (4 in) of Dry Snow.

CAUTION	Takeoff on icy runway is not recommended.

CROSSWIND

Applicable to: ALL

REPORTED BRAKING ACTION AND RUNWAY CONDITION ENTRY

It is not recommended to take off with a crosswind component higher than the one that appears in the table below:

Reported Braking Action	Reported Runway Friction Coefficient	Maximum Crosswind (kt)	Equivalent Runway Condition(2)
Good	≥ 0.4	35 kt (1)	1
Good/Medium	0.39 to 0.36	27 kt	1
Medium	0.35 to 0.3	20 kt	2/3
Medium/Poor	0.29 to 0.26	20 kt	2/3
Poor	≤ 0.25	15 kt	3/4
Unreliable		5 kt	4/5

(1) This is the maximum crosswind for dry and wet runway gust included.

(2) Equivalent runway condition (only valid in determining the maximum crosswind):

1. *Dry, damp or Wet runway covered with Water.*
2. *Runway covered with Slush.*
3. *Runway covered with Dry Snow.*
4. *Runway covered with Standing Water, with risk of hydroplaning or Wet Snow.*
5. *Icy runway or high risk of hydroplaning.*

The crosswind limitation:

- Depends on the reported braking action that the control tower provides,
- Ensures sufficient directional control during the low speed phase of takeoff roll.

RUNWAY CONDITION ENTRY

It is not recommended to take off with a crosswind component higher than the one that appears in the table below:

Runway Condition(2)	Maximum Crosswind (kt)
1	35 kt (1)
1	27 kt
2/3	20 kt
2/3	20 kt
3/4	15 kt
4/5	5 kt

(1) This is the maximum crosswind for dry and wet runway gust included.

(2) Runway condition (only valid in determining the maximum crosswind):

1. Dry, damp or Wet runway covered with Water.
2. Runway covered with Slush.
3. Runway covered with Dry Snow.
4. Runway covered with Standing Water, with risk of hydroplaning or Wet Snow.
5. Icy runway or high risk of hydroplaning.

The crosswind limitation:

- Depends on the reported braking action that the control tower provides,
- Ensures sufficient directional control during the low speed phase of takeoff roll.

REPORTED BRAKING ACTION ENTRY

It is not recommended to take off with a crosswind component higher than the one that appears in the table below:

Reported Braking Action	Reported Runway Friction Coefficient	Maximum Crosswind (kt)
Good	≥ 0.4	35 kt (1)
Good/Medium	0.39 to 0.36	27 kt
Medium	0.35 to 0.3	20 kt
Medium/Poor	0.29 to 0.26	20 kt
Poor	≤ 0.25	15 kt
Unreliable		5 kt

(1) This is the maximum crosswind for dry and wet runway gust included.

The crosswind limitation:

- Depends on the reported braking action that the control tower provides,
- Ensures sufficient directional control during the low speed phase of takeoff roll.

SPRAY INGESTION

Applicable to: ALL

During the takeoff roll and in the case of runway contamination, there is a small possibility that the engines may ingest spray of contaminant from the Nose Landing Gear (NLG) tires.
This spray of contaminant does not jeopardize the operation of the engines. The risk of ingestion does not depend on the depth of the fluid on the runway.

IN-FLT PERF APPLICATION - PLAN MODULE

Applicable to: ALL

GENERAL

OPERATIONAL FLIGHT PLAN

Before each flight, an operational flight plan - usually a Computerized Flight Plan (CFP) - has to be calculated with:

- The actual aircraft weights
- The updated performance of the aircraft
- The operating limitations
- The ATC cleared route
- The weather forecast on:
  - The route
  - The airports involved.

Apart from other pertinent information, it provides the required amount of fuel needed to perform a safe flight along the planned route, including any necessary fuel reserves.

FUEL POLICY

Adequate fuel quantity (named Block Fuel) to cover the requirements of trip, contingency, alternate, reserve and taxi must be loaded prior to departure.
At any time during a flight, the remaining Fuel On Board (FOB) must be enough to deal with the planned operation and the possible deviations.

FUEL QUANTITY CHECKS

The FOB must be periodically checked in flight. This will help the flight crew to detect possible fuel consumption higher than anticipated or a fuel leak.

PLAN

The IN-FLT PERF application is made of 6 modules (CLB, CRZ, DES, HLD, PLAN and ATMO).

The PLAN module provides the flight crew with a means to obtain fuel, time and air distance over a given ground distance for:

- Average meteorological conditions
- A given aircraft configuration including non standard ones (engines out, landing gear down)
- Various speed schedules
- Various flight planning functions (FLIGHT PLAN, IN CRUISE, ALTERNATE).

The main results of this module are:

- The fuel consumed

- The time elapsed
- The air distance covered.

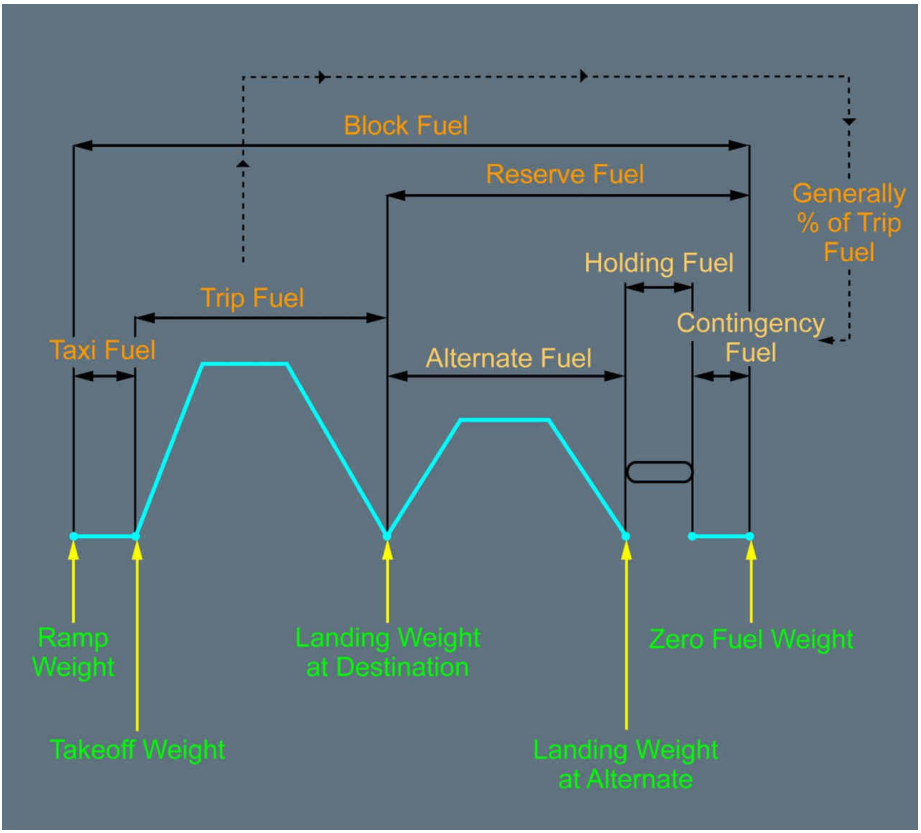
CAUTION	The Operator must not use the IN-FLT PERF PLAN module as an operational flight plan tool.

STANDARD FLIGHT PLANNING

Applicable to: ALL

The following graph illustrates the different fuel quantities for a standard flight planning.

Standard Flight Planning



BLOCK FUEL

Applicable to: ALL

GENERAL

The total fuel quantity (Block Fuel) required to fly a given sector is the sum of the following quantities:

- Taxi Fuel

L2 For more information about Taxi Fuel, *Refer to PER-IFT-FPL-MRF Taxi Fuel* .

L1 - Trip Fuel

L2 For more information about Trip Fuel, *Refer to PER-IFT-FPL-MRF Trip Fuel* .

L1 - Reserve Fuel.

L2 For more information about Reserve Fuel, *Refer to PER-IFT-FPL-MRF-RSF Reserve Fuel* .

L1 PLAN

The PLAN module does not directly provide Block Fuel.

TAXI FUEL

Applicable to: ALL

GENERAL

Taxi Fuel is the quantity of fuel expected to be used prior to takeoff (including engine start, taxi and APU consumption).

Taxi Fuel is usually a fixed quantity calculated for:

- An average taxi duration
- An average fuel consumption.

Taxi Fuel is 1 170 lb for an average taxi duration of 12 min, assuming a fuel consumption of 97 lb/min.

Note: *Maximum ramp weight may not be exceeded with Taxi Fuel on board.*

PLAN

The FLIGHT PLAN function of the PLAN module uses a fixed quantity for Taxi Fuel, depending on the Operator policy.
This value appears in the second line of the TABLE RESULTS subpanel (TAKE OFF PHASE).

TRIP FUEL

Applicable to: ALL

GENERAL

Trip Fuel is the fuel required from brake release at the departure airport to the landing touchdown at the destination airport.

Trip Fuel takes into account the necessary fuel for:
- Takeoff from the departure airport
- Climb to cruise level
- Cruise, including any step climb
- Descent
- Approach and landing at the destination airport.
  Fuel calculation is based on a consumption of 240 lb/min.
  Average quantity for 6 min IFR → 1 440 lb.

PLAN

The flight crew may use the FLIGHT PLAN function to compute Trip Fuel, according to the selected speed schedule.

RESERVE FUEL

Applicable to: ALL

RESERVE FUEL

Reserve Fuel includes the following quantities:
- Contingency Fuel ("En Route" reserve fuel)

L2 For more information about Contingency Fuel, *Refer to PER-IFT-FPL-MRF-RSF Contingency Fuel* .

L1 - Alternate Fuel

L2 For more information about Alternate Fuel, *Refer to PER-IFT-FPL-MRF-RSF Alternate Fuel* .

L1 - Holding Fuel.

L2 For more information about Holding Fuel, *Refer to PER-IFT-FPL-MRF-RSF Holding Fuel* .

CONTINGENCY FUEL

GENERAL

Contingency Fuel ("En Route" reserve fuel) depends on the Operator policy following to a national Authority approval.
Contingency Fuel is generally based on a percentage of Trip Fuel.

PLAN

The PLAN module does not compute Contingency Fuel.
If Contingency Fuel is a percentage of Trip Fuel, the flight crew may determine this value from the calculation of Trip Fuel via the FLIGHT PLAN function.

ALTERNATE FUEL

GENERAL

Alternate Fuel is the fuel required to fly from the destination airport to the alternate airport.

Alternate Fuel takes into account the necessary fuel for:
- Missed approach at the destination airport (go-around)
  Go-around allowance → 2 650 lb
- Climb from missed approach altitude
- Cruise
- Descent
- Approach and landing at the alternate airport.
  Average quantity for 4 min VFR → 970 lb.

PLAN

The flight crew may use the ALTERNATE function to compute Alternate Fuel, according to the selected speed schedule.

HOLDING FUEL

GENERAL

Holding Fuel is the minimum fuel required to fly for 30 min at 1 500 ft above the alternate airport, at holding speed in ISA conditions.
Holding Fuel is calculated with the landing weight at the alternate airport.
A conservative quantity corresponding to 30 min holding at 1 500 ft above the alternate airport in ISA conditions, at green dot speed + 25 kt in the clean configuration is 10 600 lb.

PLAN

The flight crew may calculate Holding Fuel using the FUEL computation type of the HLD module with 30 min as holding time.

APU FUEL

Applicable to: ALL

During ground operations, the APU fuel consumption is about:
- 1 135 lb/h Packs ON and APU GEN ON, or
- 1 035 lb/h APU GEN ON.

Intentionally left blank

PLAN MODULE INTERFACE

Applicable to: ALL

IN-FLT PERF PLAN Module Interface

CONDITIONS

The flight crew can define the average outside conditions and the aircraft configuration.
For more information about the CONDITIONS panel, *Refer to PER-IFT-FPL-CDT CONDITIONS Panel* .

FLIGHT DATA

The flight crew can define the data of the flight.
For more information about the FLIGHT DATA panel, *Refer to PER-IFT-FPL-FLD FLIGHT DATA Panel* .

AIRCRAFT STATUS

The flight crew can select CDL items and non standard configuration items.
For more information about the AIRCRAFT STATUS panel, *Refer to PER-IFT-ACS AIRCRAFT STATUS Panel* .

RESULTS

The RESULTS panel displays the essential information for the flight.

For more information about the RESULTS panel, refer to PLAN Results.

CONDITIONS PANEL

Applicable to: ALL

The CONDITIONS panel includes the following information:

- Average wind
- Temperature (Δ ISA)
- Anti-ice
- Initial weight
- Average CG
- Airflow.

CONDITIONS Panel

AVERAGE WIND

Applicable to: ALL

GENERAL

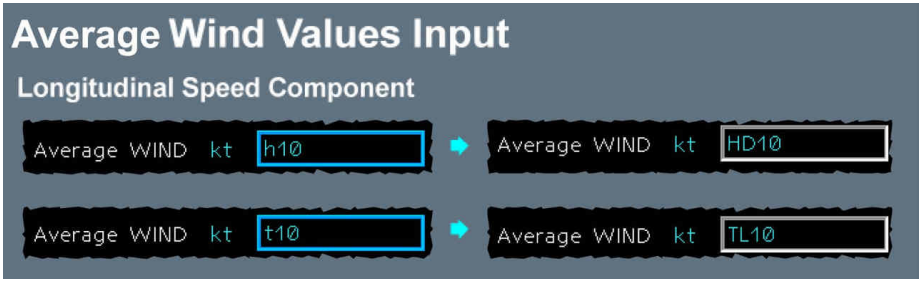
The wind affects the air distance, and therefore:
- The time to cover a given ground distance
- The fuel to cover a given ground distance.

A tailwind, as average wind, will induce:
- A decrease in the fuel consumed
- A decrease in the time elapsed
- A decrease in the air distance covered.

On the contrary, a headwind, as average wind, will induce:
- An increase in the fuel consumed
- An increase in the time elapsed
- An increase in the air distance covered.

PLAN

Average Wind Values Input



The flight crew directly enters a longitudinal average wind value for the flight.
The flight crew can use the codes “H” for a headwind and “T” for a tailwind.
The flight crew can also use the codes “HD” for a headwind and “TL” for a tailwind.

TEMPERATURE

Applicable to: ALL

GENERAL

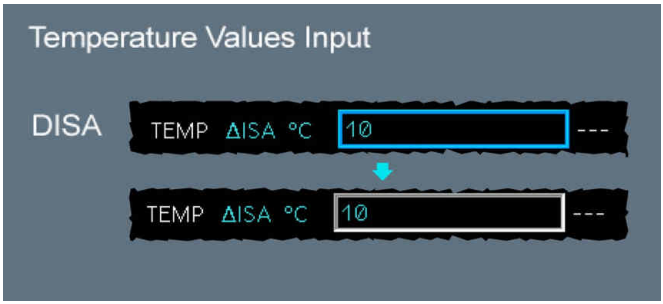
An increase in temperature leads to:

- An increase in the fuel consumed to cover a given ground distance
- A decrease in the time elapsed to cover a given ground distance.

L2 At given Mach, the True Air Speed (TAS) increases with temperature.

L1 PLAN

Temperature Values Input



The TEMP field corresponds to a deviation from ISA law (ΔISA).
The flight crew enters a temperature as a ΔISA.

ANTI-ICE

Applicable to: ALL

GENERAL

In the case of ENG and/or WING anti-ice:
- Fuel increases to cover a given ground distance
- Time increases to cover a given ground distance (only for a LRC speed cruise phase).

L2 The LRC Mach decreases, and so the True Air Speed (TAS).

L1 IN-FLT PERF

IN-FLT PERF has four anti-ice options:
- Off
- Engine
- Total
- Severe Icing.

The flight crew may use the Severe Icing option to assess the impact of ice accretion on fuel consumption and ceilings.

INITIAL WEIGHT

Applicable to: ALL

GENERAL

Any increase in the initial weight leads to:
- An increase in the fuel consumed to cover a given ground distance
- A slight increase in the time elapsed at fixed Mach to cover a given ground distance.

L2 The climb (if performed) and descent time increase with weight.

L1 PLAN

The initial weight must be between the Operating Empty Weight (OEW) and the Maximum Design Takeoff Weight (MTOW).

IN CRUISE

The flight crew enters the actual aircraft weight.

FLIGHT

The flight crew enters the aircraft weight at engine start.

ALTERNATE

The flight crew enters the aircraft weight at go-around.

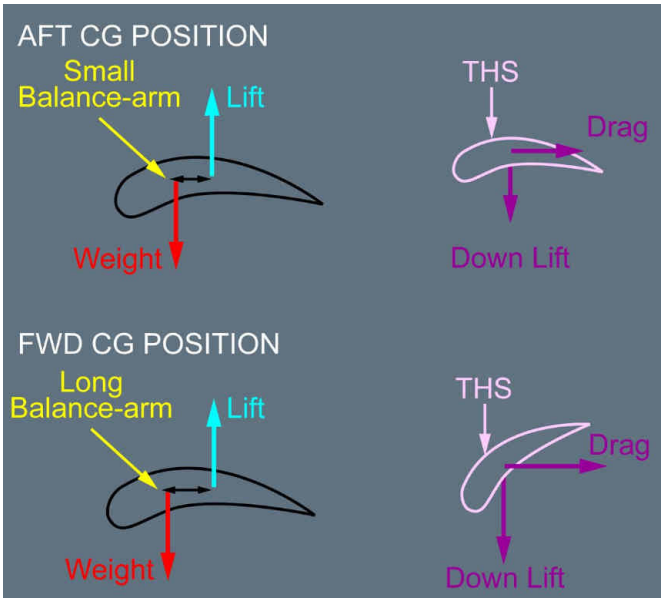
AVERAGE CG

Applicable to: ALL

GENERAL

The Center of Gravity (CG) position impacts the forces applied on the aircraft. As a result, it impacts aircraft performance.

CG Position



L2 In order to keep the aircraft level, the Trimmable Horizontal Stabilizer (THS) creates a downward force that counters the pitch down moment due to the distance between the center of lift and the center of gravity. The larger this lever arm, the higher the down lift that must be generated by the THS, and the higher the drag.

L1 PLAN

The flight crew enters an average value of the CG for the flight.
This CG is expressed in % of the Mean Aerodynamic Chord (MAC).

AIRFLOW

Applicable to: ALL

GENERAL

In the case of an increase in airflow:
- Fuel increases to cover a given ground distance
- Time increases to cover a given ground distance (only for a LRC speed cruise phase).

L2 The LRC Mach decreases, and so the True Air Speed (TAS).

L1 IN-FLT PERF

IN-FLT PERF has five airflow options:
- OFF
- LO
- MAN
- NORM
- HI.

IMPACT OF FWD CARGO COOLING

When FWD cargo cooling is active, the airflow automatically increases, and so the engine bleed.
The IN-FLT PERF airflow settings reflect the engine bleed with FWD cargo cooling OFF.
The flight crew applies the following equivalences to obtain an engine bleed that considers the effect of FWD cargo cooling:

ENG OPERATIVE	AIR FLOW Selector	FWD Cargo Cooling	Select IN-FLT PERF setting
4	LO	ON	MAN
	MAN		HI
	NORM		HI
	HI		HI
3	LO	ON	MAN
	MAN		MAN
	NORM		NORM
	HI		HI
2	LO	ON	LO
	MAN		MAN
	NORM		NORM
	HI		HI

FLIGHT DATA PANEL

Applicable to: ALL

The FLIGHT DATA panel includes the following information:

- Computation type
- Distance
- Altitude rule
- Speed type
- Engines operative
- Fuel factor.

FLIGHT DATA Panel

COMPUTATION TYPE

Applicable to: ALL

The flight crew uses the COMPUTATION TYPE drop-down list to define the desired flight planning type, whether he wishes to obtain performance for a complete flight, or over the remaining distance.

For more information about the flight planning types:
- *Refer to In Cruise*
- *Refer to Flight Plan*
- *Refer to Alternate* .

DISTANCE

Applicable to: ALL

IN CRUISE

The flight crew enters the remaining ground distance to:
- The destination airport, or
- A diversion airport, or
- The alternate airport.

FLIGHT PLAN

The flight crew enters the ground distance from the departure airport to the destination airport or a potential diversion airport.

ALTERNATE

The flight crew enters the ground distance from the destination airport to the alternate airport.

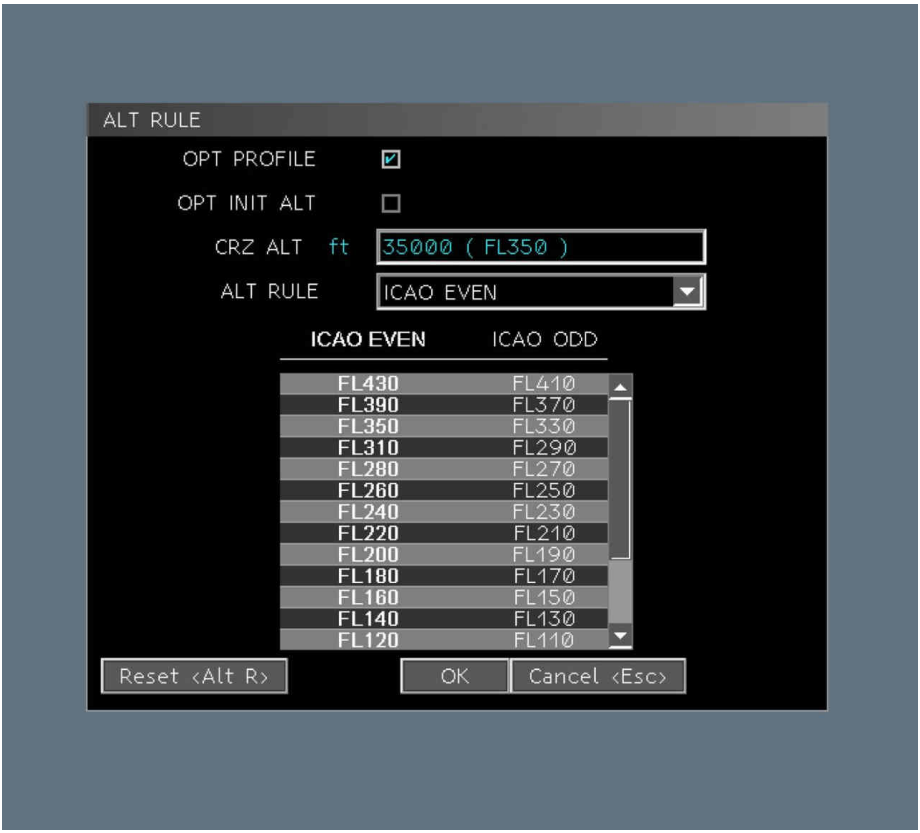
ALTITUDE RULE

Applicable to: ALL

The ALT RULE subpanel includes the following information:

- OPT PROFILE option
- OPT INIT ALT option
- Cruise altitude
- Altitude rule.

ALT PROFILE Subanel



CRUISE ALTITUDE

GENERAL

The best way to optimize fuel is to fly as close as possible to the optimum altitude, following to a given altitude rule.

PLAN

IN CRUISE

The flight crew may compute:
- At constant cruise altitude, or
- By optimizing the cruise profile, with optimum step climbs, using the OPT PROFILE option.

FLIGHT PLAN

The flight crew may compute:
- With an initial fixed cruise altitude
  - At constant cruise altitude, or
  - By optimizing the cruise profile, with optimum step climbs, using the OPT PROFILE option.

L2 If the initial fixed cruise altitude is below the optimum altitude, the optimization of the cruise profile leads to an initial cruise altitude equal to the optimum altitude.

L1 - With the initial optimum cruise altitude, using the OPT INIT ALT option
  - At constant cruise altitude, or
  - By optimizing the cruise profile, with optimum step climbs, using the OPT PROFILE option.

ALTERNATE

The flight crew may compute:
- With an initial fixed cruise altitude
- With the initial optimum cruise altitude, using the OPT INIT ALT option.

ALTITUDE RULES

GENERAL

The altitude rule defines which flight levels may be used in a given region, depending on the aircraft heading.

IN-FLT PERF

IN-FLT PERF provides the following altitude rules:
- ICAO EVEN
- ICAO ODD
- RVSM EVEN
- RVSM ODD
- CHINA EVEN (metric)
- CHINA ODD (metric)
- RUSSIA EVEN (metric)
- RUSSIA ODD (metric).

The field defaults to the first applicable altitude rule identified from the above list, depending on the selected pressure altitude.

SPEED TYPE

Applicable to: ALL

The flight crew uses the SPD TYPE drop-down list to define his speed schedule.

For more information about the speed types:
- *Refer to In Cruise*
- *Refer to Flight Plan*
- *Refer to Alternate* .

ENGINES OPERATIVE

Applicable to: ALL

GENERAL

The number of engines operative determines the thrust available to perform each flight phase and therefore largely impacts the flight planning.

PLAN

The flight crew selects the number of engines operative:

- 4 (ALL), or
- 3, or
- 2.

FUEL FACTOR

Applicable to: ALL

GENERAL

The performance factor for FMS predictions (FMS PERF FACTOR) is the sum of the Basic FMS PERF FACTOR and the Monitored Fuel Factor.

BASIC FMS PERF FACTOR

The Basic FMS PERF FACTOR correction is applied when the aircraft FMS database does not exactly fit to the aircraft model. It is published for each FMS Performance Data Base (PDB).
It results in FMS predictions consistent with the level reflected by the uncorrected IN-FLT PERF application, also called the book level.

MONITORED FUEL FACTOR

The actual airframe drag and engine performance deviate from the nominal model due to the aircraft's aging process.
The Monitored Fuel Factor is used to correct the performance book level to the actual performance level in order to permit realistic fuel predictions.
The Monitored Fuel Factor is defined as a percentage increase or decrease of the nominal Specific Range (SR) value.

IN-FLT PERF

The IN-FLT PERF fuel factor corresponds to the sum of:
- The Monitored Fuel Factor, and
- A positive performance prediction adjustment (if enabled, and at flight crew discretion).

L2 This allows the flight crew to adjust performance predictions to a drag increase due to non-quantified aerodynamic sources.

L1 When no such performance adjustment is required, the IN-FLT PERF fuel factor may thus differ from the FMS one by the Basic FMS PERF FACTOR.

Intentionally left blank

General

GENERAL

Applicable to: ALL

GENERAL

In flight, the flight crew must periodically check that the Fuel On Board (FOB) is enough to complete the planned operation.

PLAN

The flight crew may use the IN CRUISE function:

- During cruise, to assess:
  - The Estimated Fuel On Board (EFOB) at the destination airport
  - The EFOB at a potential diversion airport.
- During alternate cruise, to assess the EFOB at the alternate airport
- During diversion, to assess the EFOB at a diversion airport.

The IN CRUISE function does not directly provide an EFOB but a cumulated fuel burnt over a given straight distance.
The flight crew has to substract the cumulated fuel burnt from the actual FOB, to assess the EFOB at the corresponding airport.

The cruise phase of an IN CRUISE calculation is either:

- An optimum profile (with optimum step climbs) from a fixed cruise altitude, or
- A cruise at constant altitude.

Intentionally left blank

ECON (CI) - AEO

OPTIMUM PROFILE

Applicable to: ALL

An IN CRUISE ECON (CI) planning with optimum cruise profile is divided into several flight phases:

- An ECON (CI) cruise phase at initial altitude
- A potential step climb up to the first flight level (of the chosen altitude rule) above the initial cruise altitude, if this flight level becomes optimum (in terms of cost function) compared to the initial cruise altitude

L2 The step climb is performed at the first ECON cruise Mach of the next cruise phase.

L1 - A potential ECON (CI) cruise phase at the new cruise altitude

- Other potential step climbs and ECON (CI) cruise phases, when above flight levels (of the chosen altitude rule) become better than the current one
- An ECON (CI) descent, with the following descent law:
  - ECON descent Mach, which is the ECON cruise Mach at T/D
  - ECON descent CAS, which is a function of CI, gross weight at T/D, last cruise altitude
  - 250 kt from 10 000 ft to 1 500 ft.
- A standard approach and landing.

CONSTANT ALTITUDE

Applicable to: ALL

An IN CRUISE ECON (CI) planning at constant altitude is divided into three main flight phases:

- An ECON (CI) cruise phase at constant altitude
- An ECON (CI) descent, with the following descent law:
  - ECON descent Mach, which is the ECON cruise Mach at T/D
  - ECON descent CAS, which is a function of CI, gross weight at T/D, cruise altitude
  - 250 kt from 10 000 ft to 1 500 ft.
- A standard approach and landing.

Intentionally left blank

Fixed Speed - AEO

OPTIMUM PROFILE

Applicable to: ALL

An IN CRUISE Fixed Speed planning with optimum cruise profile is divided into several flight phases:

- A cruise phase at initial altitude and constant input Mach or CAS
- A potential step climb up to the first flight level (of the chosen altitude rule) above the initial cruise altitude, if this flight level becomes optimum (in terms of SR) compared to the initial cruise altitude

L2 The step climb is performed at the Mach or CAS of the standard climb speed profile.

L1 - A potential cruise phase at the new cruise altitude and constant input Mach or CAS

- Other potential step climbs and cruise phases, when above flight levels (of the chosen altitude rule) become better than the current one
- A descent at standard descent speed profile
- A standard approach and landing.

CONSTANT ALTITUDE

Applicable to: ALL

An IN CRUISE Fixed Speed planning at constant altitude is divided into three main flight phases:

- A cruise phase at constant altitude and constant input Mach or CAS
- A descent at standard descent speed profile
- A standard approach and landing.

Intentionally left blank

LRC Speed - AEO

OPTIMUM PROFILE

Applicable to: ALL

An IN CRUISE LRC Speed planning with optimum cruise profile is divided into several flight phases:

- A cruise phase at initial altitude and LRC speed
- A potential step climb up to the first flight level (of the chosen altitude rule) above the initial cruise altitude, if this flight level becomes optimum (in terms of SR) compared to the initial cruise altitude

L2 The step climb is performed at the Mach or CAS of the standard climb speed profile.

L1 - A potential cruise phase the at new cruise altitude and LRC speed

- Other potential step climbs and cruise phases, when above flight levels (of the chosen altitude rule) become better than the current one
- A descent at standard descent speed profile
- A standard approach and landing.

CONSTANT ALTITUDE

Applicable to: ALL

An IN CRUISE LRC Speed planning at constant altitude is divided into three main flight phases:

- A cruise phase at constant altitude and LRC speed
- A descent at standard descent speed profile
- A standard approach and landing.

Intentionally left blank

Green Dot Speed - AEO

OPTIMUM PROFILE

Applicable to: ALL

An IN CRUISE Green Dot Speed planning with optimum cruise profile is divided into several flight phases:

- A cruise phase at initial altitude and green dot speed
- A potential step climb up to the first flight level (of the chosen altitude rule) above the initial cruise altitude, if this flight level becomes optimum (in terms of SR) compared to the initial cruise altitude

L2 The step climb is performed at green dot speed.

L1 - A potential cruise phase at the new cruise altitude and green dot speed

- Other potential step climbs and cruise phases, when above flight levels (of the chosen altitude rule) become better than the current one
- A descent at standard descent speed profile
- A standard approach and landing.

CONSTANT ALTITUDE

Applicable to: ALL

An IN CRUISE Green Dot Speed planning at constant altitude is divided into three main flight phases:

- A cruise phase at constant altitude and at green dot speed
- A descent at standard descent speed profile
- A standard approach and landing.

Intentionally left blank

Turbulence Speed - AEO

OPTIMUM PROFILE

Applicable to: ALL

An IN CRUISE Turbulence Speed planning with optimum cruise profile is divided into several flight phases:

- A cruise phase at initial altitude and turbulence speed
- A potential step climb up to the first flight level (of the chosen altitude rule) above the initial cruise altitude, if this flight level becomes optimum (in terms of SR) compared to the initial cruise altitude

L2 The step climb is performed at the Mach or CAS of the turbulence climb speed profile.

L1 - A potential cruise phase at the new cruise altitude and turbulence speed

- Other potential step climbs and cruise phases, when above flight levels (of the chosen altitude rule) become better than the current one
- A descent at turbulence descent speed profile
- A standard approach and landing.

CONSTANT ALTITUDE

Applicable to: ALL

An IN CRUISE Turbulence Speed planning at constant altitude is divided into three main flight phases:

- A cruise phase at constant altitude and turbulence speed
- A descent at turbulence descent speed profile
- A standard approach and landing.

Intentionally left blank

General

GENERAL

Applicable to: ALL

GENERAL

Before any flight, the flight crew shall check that the Fuel On Board (FOB) at departure is enough, so that the Estimated Fuel On Board (EFOB) at destination is not less than the minimum recommended fuel quantities.
The FOB at departure shall not be less than the Block Fuel.

L2 For more information about the Block Fuel, *Refer to Flight Planning - Fuel* .

L1 PLAN

The flight crew may use the FLIGHT PLAN function to assess:
- The EFOB at the destination airport
- The EFOB at a potential diversion airport.

The FLIGHT PLAN function does not directly provide an EFOB but a cumulated fuel burnt over a given straight distance.
The flight crew has to substract the cumulated fuel burnt from the FOB at the departure airport, to assess the EFOB at the corresponding airport.

The initial cruise altitude of a FLIGHT PLAN calculation is either:
- The optimum altitude, or
- An input altitude.

The cruise phase of a FLIGHT PLAN calculation is either:
- An optimum profile (with optimum step climbs), or
- A cruise at constant altitude.

Intentionally left blank

ECON (CI) - AEO

OPTIMUM PROFILE FROM INITIAL OPTIMUM ALTITUDE

Applicable to: ALL

A FLIGHT PLAN ECON (CI) planning with optimum cruise profile from the initial optimum altitude is divided into several flight phases:

- A standard taxi and takeoff
- An OPEN (CI) climb, with the following climb law:
  - 250 kt from 1 500 ft to 10 000 ft
  - ECON climb CAS, which is a function of CI, predicted gross weight at T/C, first cruise altitude
  - ECON climb Mach, which is the ECON cruise Mach at T/C.
- An ECON (CI) cruise phase at the initial optimum altitude
- A potential step climb up to the first flight level (of the chosen altitude rule) above the initial optimum altitude, if this flight level becomes optimum (in terms of cost function) compared to the initial optimum altitude

L2 The step climb is performed at the first ECON cruise Mach of the next cruise phase.

L1 - A potential ECON (CI) cruise phase at the new cruise altitude

- Other potential step climbs and ECON (CI) cruise phases, when above flight levels (of the chosen altitude rule) become better than the current one
- An ECON (CI) descent, with the following descent law:
  - ECON descent Mach, which is the ECON cruise Mach at T/D
  - ECON descent CAS, which is a function of CI, gross weight at T/D, last cruise altitude
  - 250 kt from 10 000 ft to 1 500 ft.
- A standard approach and landing.

OPTIMUM PROFILE FROM INITIAL INPUT ALTITUDE

Applicable to: ALL

A FLIGHT PLAN ECON (CI) planning with optimum cruise profile from an initial input cruise altitude is divided into several flight phases:

- A standard taxi and takeoff
- An OPEN (CI) climb, with the following climb law:
  - 250 kt from 1 500 ft to 10 000 ft
  - ECON climb CAS, which is a function of CI, predicted gross weight at T/C, first cruise altitude
  - ECON climb Mach, which is the ECON cruise Mach at T/C.
- An ECON (CI) cruise phase at the input cruise altitude
- A potential step climb up to the first flight level (of the chosen altitude rule) above the input cruise altitude, if this flight level becomes optimum (in terms of cost function) compared to the input cruise altitude

L2 The step climb is performed at the first ECON cruise Mach of the next cruise phase.

L1 - A potential ECON (CI) cruise phase at the new cruise altitude

- Other potential step climbs and ECON (CI) cruise phases, when above flight levels (of the chosen altitude rule) become better than the current one
- An ECON (CI) descent, with the following descent law:
  - ECON descent Mach, which is the ECON cruise Mach at T/D
  - ECON descent CAS, which is a function of CI, gross weight at T/D, last cruise altitude
  - 250 kt from 10 000 ft to 1 500 ft.
- A standard approach and landing.

CONSTANT ALTITUDE FROM INITIAL OPTIMUM ALTITUDE

Applicable to: ALL

A FLIGHT PLAN ECON (CI) planning at constant cruise altitude from the initial optimum altitude is divided into five flight phases:

- A standard taxi and takeoff
- An OPEN (CI) climb, with the following climb law:
  - 250 kt from 1 500 ft to 10 000 ft
  - ECON climb CAS, which is a function of CI, predicted gross weight at T/C, cruise altitude
  - ECON climb Mach, which is the ECON cruise Mach at T/C.
- An ECON (CI) cruise phase at the initial optimum altitude
- An ECON (CI) descent, with the following descent law:
  - ECON descent Mach, which is the ECON cruise Mach at T/D
  - ECON descent CAS, which is a function of CI, gross weight at T/D, cruise altitude
  - 250 kt from 10 000 ft to 1 500 ft.
- A standard approach and landing.

CONSTANT ALTITUDE FROM INITIAL INPUT ALTITUDE

Applicable to: ALL

A FLIGHT PLAN ECON (CI) planning at constant cruise altitude from an initial input cruise altitude is divided into five flight phases:

- A standard taxi and takeoff
- An OPEN (CI) climb, with the following climb law:
  - 250 kt from 1 500 ft to 10 000 ft
  - ECON climb CAS, which is a function of CI, predicted gross weight at T/C, input cruise altitude
  - ECON climb Mach, which is the ECON cruise Mach at T/C.
- An ECON (CI) cruise phase at the input cruise altitude
- An ECON (CI) descent, with the following descent law:
  - ECON descent Mach, which is the ECON cruise Mach at T/D
  - ECON descent CAS, which is a function of CI, gross weight at T/D, input cruise altitude
  - 250 kt from 10 000 ft to 1 500 ft.
- A standard approach and landing.

Intentionally left blank

Fixed Speed - AEO

OPTIMUM PROFILE FROM INITIAL OPTIMUM ALTITUDE

Applicable to: ALL

A FLIGHT PLAN Fixed Speed planning with optimum cruise profile from the initial optimum altitude is divided into several flight phases:

- A standard taxi and takeoff
- A climb at standard climb speed profile
- A cruise phase at the initial optimum altitude and constant input Mach or CAS
- A potential step climb up to the first flight level (of the chosen altitude rule) above the initial optimum altitude, if this flight level becomes optimum (in terms of SR) compared to the initial optimum altitude

L2 The step climb is performed at the Mach or CAS of the standard climb speed profile.

L1 - A potential cruise phase at the new cruise altitude and constant input Mach or CAS

- Other potential step climbs and cruise phases, when above flight levels (of the chosen altitude rule) become better than the current one
- A descent at standard descent speed profile
- A standard approach and landing.

OPTIMUM PROFILE FROM INITIAL INPUT ALTITUDE

Applicable to: ALL

A FLIGHT PLAN Fixed Speed planning with optimum cruise profile from an initial input cruise altitude is divided into several flight phases:

- A standard taxi and takeoff
- A climb at standard climb speed profile
- A cruise phase at the input cruise altitude and constant input Mach or CAS
- A potential step climb up to the first flight level (of the chosen altitude rule) above the input cruise altitude, if this flight level becomes optimum (in terms of SR) compared to the input cruise altitude

L2 The step climb is performed at the Mach or CAS of the standard climb speed profile.

L1 - A potential cruise phase at the new cruise altitude and constant input Mach or CAS

- Other potential step climbs and cruise phases, when above flight levels (of the chosen altitude rule) become better than the current one
- A descent at standard descent speed profile
- A standard approach and landing.

CONSTANT ALTITUDE FROM INITIAL OPTIMUM ALTITUDE

Applicable to: ALL

A FLIGHT PLAN Fixed Speed planning with constant cruise altitude from the initial optimum altitude is divided into five flight phases:

- A standard taxi and takeoff
- A climb at standard climb speed profile
- A cruise phase at the initial optimum altitude and constant input Mach or CAS
- A descent at standard descent speed profile
- A standard approach and landing.

CONSTANT ALTITUDE FROM INITIAL INPUT ALTITUDE

Applicable to: ALL

A FLIGHT PLAN Fixed Speed planning with constant cruise altitude from an input cruise altitude is divided into five flight phases:

- A standard taxi and takeoff
- A climb at standard climb speed profile
- A cruise phase at the input cruise altitude and constant input Mach or CAS
- A descent at standard descent speed profile
- A standard approach and landing.

LRC Speed - AEO

OPTIMUM PROFILE FROM INITIAL OPTIMUM ALTITUDE

Applicable to: ALL

A FLIGHT PLAN LRC Speed planning with optimum cruise profile from the initial optimum altitude is divided into several flight phases:

- A standard taxi and takeoff
- A climb at standard climb speed profile
- A cruise phase at the initial optimum altitude and LRC speed
- A potential step climb up to the first flight level (of the chosen altitude rule) above the initial optimum altitude, if this flight level becomes optimum (in terms of SR) compared to the initial optimum altitude

L2 The step climb is performed at the Mach or CAS of the standard climb speed profile.

L1 - A potential cruise phase at the new cruise altitude and LRC speed

- Other potential step climbs and cruise phases, when above flight levels (of the chosen altitude rule) become better than the current one
- A descent at standard descent speed profile
- A standard approach and landing.

OPTIMUM PROFILE FROM INITIAL INPUT ALTITUDE

Applicable to: ALL

A FLIGHT PLAN LRC Speed planning with optimum cruise profile from an initial input cruise altitude is divided into several flight phases:

- A standard taxi and takeoff
- A climb at standard climb speed profile
- A cruise phase at the input cruise altitude and LRC speed
- A potential step climb up to the first flight level (of the chosen altitude rule) above the input cruise altitude, if this flight level becomes optimum (in terms of SR) compared to the input cruise altitude

L2 The step climb is performed at the Mach or CAS of the standard climb speed profile.

L1 - A potential cruise phase at the new cruise altitude and LRC speed

- Other potential step climbs and cruise phases, when above flight levels (of the chosen altitude rule) become better than the current one
- A descent at standard descent speed profile
- A standard approach and landing.

CONSTANT ALTITUDE FROM INITIAL OPTIMUM ALTITUDE

Applicable to: ALL

A FLIGHT PLAN LRC Speed planning with constant cruise altitude from the initial optimum altitude is divided into five flight phases:

- A standard taxi and takeoff
- A climb at standard climb speed profile
- A cruise phase at the initial optimum altitude and LRC speed
- A descent at standard descent speed profile
- A standard approach and landing.

CONSTANT ALTITUDE FROM INITIAL INPUT ALTITUDE

Applicable to: ALL

A FLIGHT PLAN LRC Speed planning with constant cruise altitude from an input cruise altitude is divided into five flight phases:

- A standard taxi and takeoff
- A climb at standard climb speed profile
- A cruise phase at the input cruise altitude and LRC speed
- A descent at standard descent speed profile
- A standard approach and landing.

Green Dot Speed - AEO

OPTIMUM PROFILE FROM INITIAL OPTIMUM ALTITUDE

Applicable to: ALL

A FLIGHT PLAN Green Dot Speed planning with optimum cruise profile from the initial optimum altitude is divided into several flight phases:

- A standard taxi and takeoff
- A climb at green dot speed
- A cruise phase at the initial optimum altitude and green dot speed
- A potential step climb up to the first flight level (of the chosen altitude rule) above the initial optimum altitude, if this flight level becomes optimum (in terms of SR) compared to the initial optimum altitude

L2 The step climb is performed at green dot speed.

L1 - A potential cruise phase at the new cruise altitude and green dot speed

- Other potential step climbs and cruise phases, when above flight levels (of the chosen altitude rule) become better than the current one
- A descent at standard descent speed profile
- A standard approach and landing.

OPTIMUM PROFILE FROM INITIAL INPUT ALTITUDE

Applicable to: ALL

A FLIGHT PLAN Green Dot Speed planning with optimum cruise profile from an initial input cruise altitude is divided into several flight phases:

- A standard taxi and takeoff
- A climb at green dot speed
- A cruise phase at the input cruise altitude and green dot speed
- A potential step climb up to the first flight level (of the chosen altitude rule) above the input cruise altitude, if this flight level becomes optimum (in terms of SR) compared to the input cruise altitude

L2 The step climb is performed at green dot speed.

L1 - A potential cruise phase at the new cruise altitude and green dot speed

- Other potential step climbs and cruise phases, when above flight levels (of the chosen altitude rule) become better than the current one
- A descent at standard descent speed profile
- A standard approach and landing.

CONSTANT ALTITUDE FROM INITIAL OPTIMUM ALTITUDE

Applicable to: ALL

A FLIGHT PLAN Green Dot Speed planning with constant cruise altitude from the initial optimum altitude is divided into five flight phases:

- A standard taxi and takeoff
- A climb at green dot speed
- A cruise phase at the initial optimum altitude and green dot speed
- A descent at standard descent speed profile
- A standard approach and landing.

CONSTANT ALTITUDE FROM INITIAL INPUT ALTITUDE

Applicable to: ALL

A FLIGHT PLAN Green Dot Speed planning with constant cruise altitude from an initial input cruise altitude is divided into five flight phases:

- A standard taxi and takeoff
- A climb at green dot speed
- A cruise phase at the input cruise altitude and green dot speed
- A descent at standard descent speed profile
- A standard approach and landing.

Turbulence Speed - AEO

OPTIMUM PROFILE FROM INITIAL OPTIMUM ALTITUDE

Applicable to: ALL

A FLIGHT PLAN Turbulence Speed planning with optimum cruise profile from the initial optimum altitude is divided into several flight phases:

- A standard taxi and takeoff
- A climb at turbulence climb speed profile
- A cruise phase at the initial optimum altitude and turbulence speed
- A potential step climb up to the first flight level (of the chosen altitude rule) above the initial optimum altitude, if this flight level becomes optimum (in terms of SR) compared to the initial optimum altitude

L2 The step climb is performed at the Mach or CAS of the turbulence climb speed profile.

L1 - A potential cruise phase at new cruise altitude and turbulence speed

- Other potential step climbs and cruise phases, when above flight levels (of the chosen altitude rule) become better than the current one
- A descent at turbulence descent speed profile
- A standard approach and landing.

OPTIMUM PROFILE FROM INITIAL INPUT ALTITUDE

Applicable to: ALL

A FLIGHT PLAN Turbulence Speed planning with optimum cruise profile from an initial input cruise altitude is divided into several flight phases:

- A standard taxi and takeoff
- A climb at turbulence climb speed profile
- A cruise phase at the input cruise altitude and turbulence speed
- A potential step climb up to the first flight level (of the chosen altitude rule) above the input cruise altitude, if this flight level becomes optimum (in terms of SR) compared to the input cruise altitude

L2 The step climb is performed at the Mach or CAS of the turbulence climb speed profile.

L1 - A potential cruise phase at the new cruise altitude and turbulence speed

- Other potential step climbs and cruise phases, when above flight levels (of the chosen altitude rule) become better than the current one
- A descent at turbulence descent speed profile
- A standard approach and landing.

CONSTANT ALTITUDE FROM INITIAL OPTIMUM ALTITUDE

Applicable to: ALL

A FLIGHT PLAN Turbulence Speed planning with constant cruise altitude from the initial optimum altitude is divided into five flight phases:

- A standard taxi and takeoff
- A climb at turbulence climb speed profile
- A cruise phase at the initial optimum altitude and turbulence speed
- A descent at turbulence descent speed profile
- A standard approach and landing.

CONSTANT ALTITUDE FROM INITIAL INPUT ALTITUDE

Applicable to: ALL

A FLIGHT PLAN Turbulence Speed planning with constant cruise altitude from an input cruise altitude is divided into five flight phases:

- A standard taxi and takeoff
- A climb at turbulence climb speed profile
- A cruise phase at the input cruise altitude and turbulence speed
- A descent at turbulence descent speed profile
- A standard approach and landing.

General

GENERAL

Applicable to: ALL

GENERAL

The Fuel On Board (FOB) at departure shall not be less than the Block Fuel.
Alternate Fuel is a part of the Block Fuel.

L2 For more information about the Alternate Fuel, *Refer to PER-IFT-FPL-MRF-RSF Alternate Fuel* .

L1 PLAN

The flight crew may use the ALTERNATE function to estimate Alternate Fuel.

The cruise altitude of an ALTERNATE calculation is either:

- The initial optimum altitude, or
- An input altitude.

Intentionally left blank

ECON (CI) - AEO

OPTIMUM ALTITUDE

Applicable to: ALL

An ALTERNATE ECON (CI) planning at initial optimum altitude is divided into five flight phases:

- A standard missed approach (go-around)
- An OPEN (CI) climb, with the following climb law:
  - 250 kt from 1 500 ft to 10 000 ft
  - ECON climb CAS, which is a function of CI, predicted gross weight at T/C, cruise altitude
  - ECON climb Mach, which is the ECON cruise Mach at T/C.
- An ECON (CI) cruise phase at the initial optimum altitude
- An ECON (CI) descent, with the following descent law:
  - ECON descent Mach, which is the ECON cruise Mach at T/D
  - ECON descent CAS, which is a function of CI, gross weight at T/D, cruise altitude
  - 250 kt from 10 000 ft to 1 500 ft.
- A standard approach and landing.

INPUT ALTITUDE

Applicable to: ALL

An ALTERNATE ECON (CI) planning at input cruise altitude is divided into five flight phases:

- A standard missed approach
- An OPEN (CI) climb, with the following climb law:
  - 250 kt from 1 500 ft to 10 000 ft
  - ECON climb CAS, which is a function of CI, predicted gross weight at T/C, input cruise altitude
  - ECON climb Mach, which is the ECON cruise Mach at T/C.
- An ECON (CI) cruise phase at the input cruise altitude
- An ECON (CI) descent, with the following descent law:
  - ECON descent Mach, which is the ECON cruise Mach at T/D
  - ECON descent CAS, which is a function of CI, gross weight at T/D, input cruise altitude
  - 250 kt from 10 000 ft to 1 500 ft.
- A standard approach and landing.

Intentionally left blank

Fixed Speed - AEO

OPTIMUM ALTITUDE

Applicable to: ALL

An ALTERNATE Fixed Speed planning at initial optimum altitude is divided into five flight phases:
- A standard missed approach (go-around)
- A climb at standard climb speed profile
- A cruise phase at the initial optimum altitude and constant input Mach or CAS
- A descent at standard descent speed profile
- A standard approach and landing.

INPUT ALTITUDE

Applicable to: ALL

An ALTERNATE Fixed Speed planning at input cruise altitude is divided into five flight phases:
- A standard missed approach (go-around)
- A climb at standard climb speed profile
- A cruise phase at the input cruise altitude and constant input Mach or CAS
- A descent at standard descent speed profile
- A standard approach and landing.

Intentionally left blank

LRC Speed - AEO

OPTIMUM ALTITUDE

Applicable to: ALL

An ALTERNATE LRC Speed planning at initial optimum altitude is divided into five flight phases:
- A standard missed approach (go-around)
- A climb at standard climb speed profile
- A cruise phase at the initial optimum altitude and LRC speed
- A descent at standard descent speed profile
- A standard approach and landing.

INPUT ALTITUDE

Applicable to: ALL

An ALTERNATE LRC Speed planning at input cruise altitude is divided into five flight phases:
- A standard missed approach (go-around)
- A climb at standard climb speed profile
- A cruise phase at the input cruise altitude and LRC speed
- A descent at standard descent speed profile
- A standard approach and landing.

Intentionally left blank

Green Dot Speed - AEO

OPTIMUM ALTITUDE

Applicable to: ALL

An ALTERNATE Green Dot Speed planning at initial optimum altitude is divided into five flight phases:

- A standard missed approach (go-around)
- A climb at green dot speed
- A cruise phase at the initial optimum altitude and green dot speed
- A descent at standard descent speed profile
- A standard approach and landing.

INPUT ALTITUDE

Applicable to: ALL

An ALTERNATE Green Dot Speed planning at input cruise altitude is divided into five flight phases:

- A standard missed approach (go-around)
- A climb at green dot speed
- A cruise phase at the input cruise altitude and green dot speed
- A descent at standard descent speed profile
- A standard approach and landing.

Intentionally left blank

Turbulence Speed - AEO

OPTIMUM ALTITUDE

Applicable to: ALL

An ALTERNATE Turbulence Speed planning at initial optimum altitude is divided into five flight phases:

- A standard missed approach (go-around)
- A climb at turbulence climb speed profile
- A cruise phase at the initial optimum altitude and turbulence speed
- A descent at turbulence descent speed profile
- A standard approach and landing.

INPUT ALTITUDE

Applicable to: ALL

An ALTERNATE Turbulence Speed planning at input cruise altitude is divided into five flight phases:

- A standard missed approach (go-around)
- A climb at turbulence climb speed profile
- A cruise phase at the input cruise altitude and turbulence speed
- A descent at turbulence descent speed profile
- A standard approach and landing.

Intentionally left blank

BASIC RESULTS PANEL

Applicable to: ALL

The basic RESULTS panel provides the essential information for the flight planning.

IN CRUISE

Basic RESULTS Panel

TRIP FUEL is the fuel burnt from the start of the IN CRUISE calculation to:
- The destination airport, or
- A diversion airport, or
- The alternate airport (if the start of calculation is during the alternate cruise phase).

TIME is the time elapsed from the start of the IN CRUISE calculation to:
- The destination airport, or
- A diversion airport, or
- The alternate airport (if the start of calculation is during the alternate cruise phase).

AIR DIST is the air distance covered from the start of the IN CRUISE calculation to:
- The destination airport, or
- A diversion airport, or
- The alternate airport (if the start of calculation is during the alternate cruise phase).

FLIGHT PLAN

Basic RESULTS Panel

taxi+trip FUEL is the fuel burnt from the departure airport to the destination airport.
TIME is the time elapsed from the departure airport to the destination airport.
AIR DIST is the air distance covered from the departure airport to the destination airport.

ALTERNATE

Basic RESULTS Panel

ALT FUEL is the fuel burnt from the destination airport to the alternate airport.
TIME is the time elapsed from the destination airport to the alternate airport.
AIR DIST is the air distance covered from the destination airport to the alternate airport.

TABLE RESULTS SUBPANEL

Applicable to: ALL

The TABLE RESULTS subpanel provides the detailed information for the flight planning.
The parameters are given for each flight phase of the flight planning. The parameters actually displayed depend on the Operator customization.

PHASE

This column displays the phase of the flight planning.

ACCDST

This column displays the actual cumulated ground distance covered from the first phase of the flight planning to the end of the considered one.

ACCTIME

This column displays the actual cumulated time elapsed from the first phase of the flight planning to the end of the considered one.

ACCFUEL

This column displays the actual cumulated fuel burnt from the first phase of the flight planning to the end of the considered one.

ALT

This column displays the pressure altitude at the top of the flight phase.

ACCNAM

This column displays the actual cumulated air distance covered from the first phase of the flight planning to the end of the considered one.

TRKDST

This column displays the ground distance covered during each phase of the flight planning.

SEGTIME

This column displays the time elapsed during each phase of the flight planning.

SEGFUEL

This column displays the fuel burnt during each phase of the flight planning.

TRKNAM

This column displays the air distance covered during each phase of the flight planning.

GRAPH RESULTS SUBPANEL

Applicable to: ALL

The flight crew can plot flight parameters versus each other using the GRAPH RESULTS subpanel. The possible parameters depend on the Operator customization of the TABLE RESULTS. Specific values can be read from the graph using the cross-hairs.

Intentionally left blank

IN-FLT PERF APPLICATION - CLB MODULE

Applicable to: ALL

GENERAL

The climb phase starts at the end of takeoff and ends at the initial cruise level.

CLB

The IN-FLT PERF application is made of 6 modules (CLB, CRZ, DES, HLD, PLAN and ATMO).

The CLB module provides the flight crew with a means to obtain climb performance data for:
- Given meteorological conditions
- A given aircraft configuration including non standard ones (engines out, landing gear down)
- Various speed schedules.

The main results of this module are:
- Fuel, time, and distance to the Top of Climb (T/C)
- Climb ceiling.

Intentionally left blank

CLB MODULE INTERFACE

Applicable to: ALL

IN-FLT PERF CLB Module Interface

CONDITIONS

The flight crew can define the current outside conditions and the aircraft configuration.
For more information about the CONDITIONS panel, *Refer to PER-IFT-CLB-CDT CONDITIONS Panel* .

CLIMB DATA

The flight crew can define the data of the climb phase.
For more information about the CLIMB DATA panel, *Refer to PER-IFT-CLB-CBD CLIMB DATA Panel* .

AIRCRAFT STATUS

The flight crew can select CDL items and non standard configuration items.
For more information about the AIRCRAFT STATUS panel, *Refer to PER-IFT-ACS AIRCRAFT STATUS Panel* .

RESULTS

The RESULTS panel displays the essential information for the climb phase.

For more information about the RESULTS panel, refer to Climb Results.

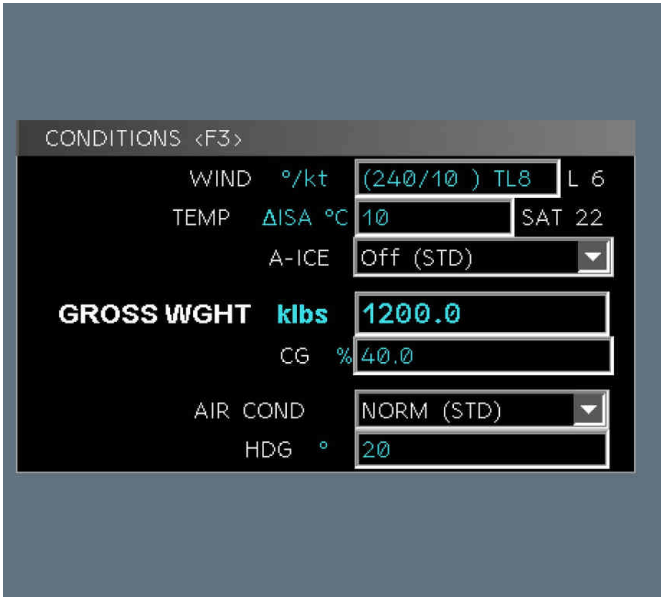
CONDITIONS PANEL

Applicable to: ALL

The CONDITIONS panel provides the following information:

- Wind
- Heading
- Temperature (Δ ISA)
- Anti-ice
- Gross weight
- CG
- Airflow.

CONDITIONS Panel



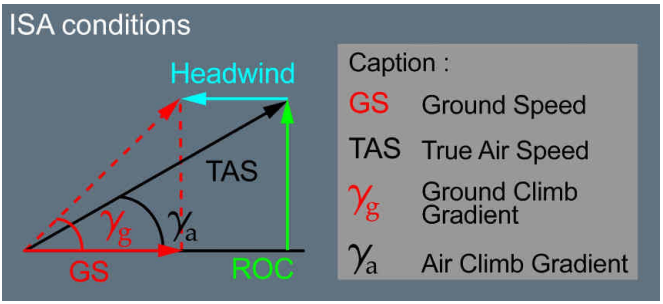
WIND

Applicable to: ALL

GENERAL

A constant wind component has no influence on the Rate of Climb (ROC), but affects the climb angle.

Headwind Effect on Climb Flight Path



L2 A headwind component increases the flight path angle and decreases the ground distance to the Top of Climb (T/C).
The air climb gradient remains unchanged, whatever the wind component. So, the fuel and the time necessary to climb form the initial altitude to the T/C stay the same.

L3 This is not applicable to a climb at Cost Index (CI), as the ECON climb Mach slightly depends on the wind.

L1 A longitudinal headwind component decreases the ground distance to reach the target pressure altitude.
Crosswind does not affect climb performance and is provided for information only.
A large and sudden increase in the tailwind with increasing altitude can significantly affect the climb capability.

CLB

There are two ways to define wind values:
- Longitudinal Speed Component
- Direction/Speed Combination.

LONGITUDINAL SPEED COMPONENT

The flight crew enters the longitudinal component with:
- H or HD followed by the headwind speed (e.g. H10 or HD5), or
- T or TL followed by the tailwind speed (e.g. T6 or TL8).

Wind Values Input - Longitudinal Speed Component

DIRECTION/SPEED COMBINATION

The flight crew enters the wind direction and the wind speed.
The entry is projected along the heading and perpendicular to the heading.
The longitudinal projection follows the same display rules as the speed entry.

IN-FLT PERF displays the crosswind as:
- R, if the wind comes from the right, or
- L, if the wind comes from the left.

Wind Values Input - Direction/Speed Combination

HEADING

Applicable to: ALL

GENERAL

The heading defines the axis on which the wind is projected.

CLB

The IN-FLT PERF heading and wind direction have to be both entered in either magnetic or true north.

The HDG field is only displayed if a wind has been entered in a combination of a direction and a speed.

L2 For more information about the wind, *Refer to Climb - Wind* .

TEMPERATURE

Applicable to: ALL

GENERAL

When temperature (SAT or ΔISA) increases, air density decreases, therefore:

- Climb gradient decreases

L2 Climb gradient mostly depends on excess thrust, which decreases with temperature.

L3 In climb, excess thrust is the difference between maximum available thrust in climb rating and drag.

Due to air density reduction, climb thrust and drag decrease. But, since the drag force decreases at a lower rate than the available thrust, the difference between thrust and drag decreases.

L1 - True Air Speed (TAS) increases

L2 At fixed Calibrated Air Speed (CAS), TAS is inversely proportional to air density, which decreases with temperature.

At fixed Mach, TAS increases with temperature.

L1 - Rate of Climb (ROC) decreases

L3 ROC is a function of climb gradient (GRDT), TAS and ΔISA.

ROC can be expressed as ROC = TAS × sin (GRDT) × f(ΔISA).

The function f(ΔISA) is equal to 1 in ISA conditions, and decreases with ΔISA.

The increment in TAS is offset by the decrement due to f(ΔISA) and GRDT.

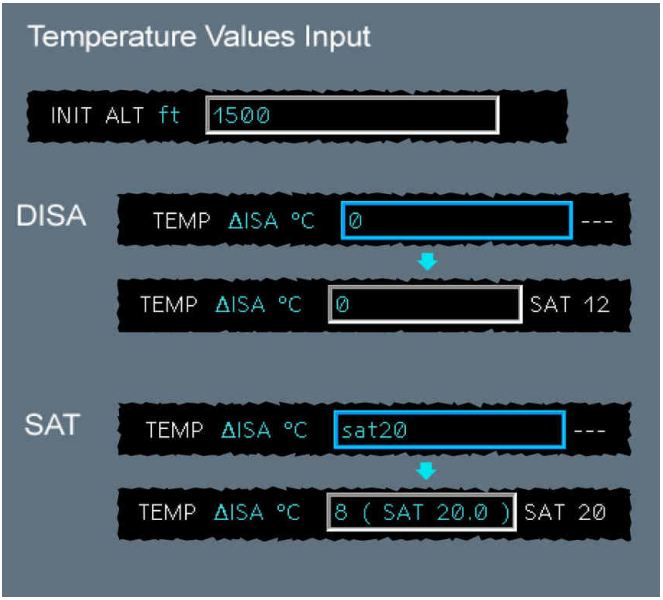
L1 - Fuel, time and distance to reach the target pressure altitude increase

- Climb ceiling is lower.

L2 As the ROC decreases at given pressure altitude, it reaches its minimum value at a lower pressure altitude.

L1 **CLB**

Temperature Values Input



The TEMP field corresponds to a deviation from ISA law (ΔISA).

The flight crew can enter a temperature as:
- A ΔISA, or
- A Static Air Temperature (SAT) at initial pressure altitude, which is automatically converted into a ΔISA.

ANTI-ICE

Applicable to: ALL

GENERAL

Anti-ice increases engine bleed and reduces available thrust.

In the case of ENG and/or WING anti-ice:

- Climb gradient and ROC decrease

L2 Climb gradient and ROC depend on thrust. Climb thrust decreases.

L1 - Fuel, time and distance to reach the target pressure altitude increase
- Climb ceiling is lower.

L2 As the ROC decreases at given pressure altitude, it reaches its minimum value at a lower pressure altitude.

L1 IN-FLT PERF

IN-FLT PERF has four anti-ice options:

- Off
- Engine
- Total
- Severe Icing.

  The flight crew may use the Severe Icing option to assess the impact of ice accretion on fuel consumption and ceilings.

GROSS WEIGHT

Applicable to: ALL

GENERAL

An increase in weight leads to:

- A decrease in climb gradient and Rate Of Climb (ROC)

L3 If TAS were constant with altitude at given CAS or Mach, climb gradient (GRDT) and ROC would be inversely proportional to the weight.

$$\sin(\mathrm{GRDT}) = \frac{(\mathrm{Thrust} - \mathrm{Drag})}{\mathrm{Weight}} - \frac{1}{g} \times \frac{d}{dt}(TAS)$$

L1 - An increase in fuel, time and distance to reach the target pressure altitude
- A lower climb ceiling.

L2 As the ROC decreases at given pressure altitude, it reaches its minimum value at a lower pressure altitude.

L1 CLB

The flight crew enters the current aircraft weight at start of climb calculation.
This gross weight (GROSS WGHT field) must be between the Operating Empty Weight (OEW) and the Maximum Design Takeoff Weight (MTOW).

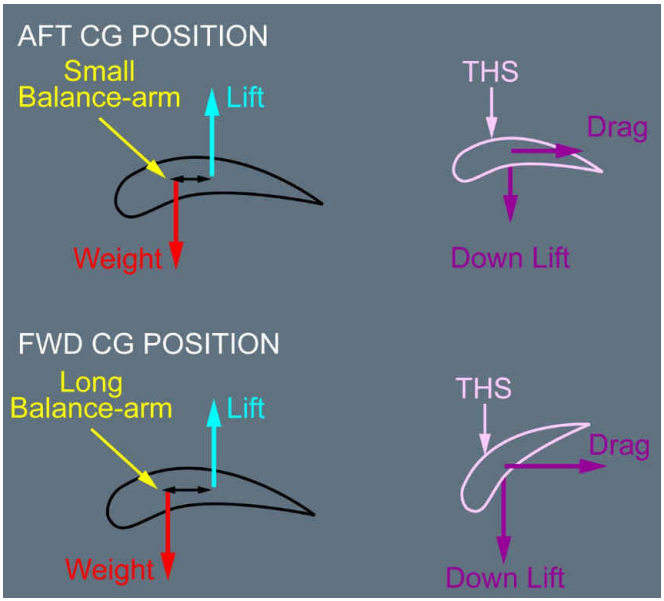
CG

Applicable to: ALL

GENERAL

The Center of Gravity (CG) position impacts the forces applied on the aircraft. As a result, it impacts aircraft performance.

CG Position



L2 In order to keep the aircraft level, the Trimmable Horizontal Stabilizer (THS) creates a downward force that counters the pitch down moment due to the distance between the center of lift and the center of gravity. The larger this lever arm, the higher the down lift that must be generated by the THS, and the higher the drag.

L1 **IN-FLT PERF**

The CG field is expressed in % of the Mean Aerodynamic Chord (MAC).

AIRFLOW

Applicable to: ALL

GENERAL

High airflow increases engine bleed and reduces available thrust.

With increased engine bleed:

- Climb gradient and ROC decrease

L2 Climb gradient and ROC depend on thrust. Climb thrust decreases.

L1 - Fuel, time and distance to reach the target pressure altitude increase

- Climb ceiling is lower.

L2 As the ROC decreases at given pressure altitude, it reaches its minimum value at a lower pressure altitude.

L1 IN-FLT PERF

IN-FLT PERF has five airflow options:

- OFF
- LO
- MAN
- NORM
- HI.

IMPACT OF FWD CARGO COOLING

When FWD cargo cooling is active, the airflow automatically increases, and so the engine bleed. The IN-FLT PERF airflow settings reflect the engine bleed with FWD cargo cooling OFF.
The flight crew applies the following equivalences to obtain an engine bleed that considers the effect of FWD cargo cooling:

ENG OPERATIVE	AIR FLOW Selector	FWD Cargo Cooling	Select IN-FLT PERF setting
4	LO	ON	MAN
	MAN		HI
	NORM		HI
	HI		HI
3	LO	ON	MAN
	MAN		MAN
	NORM		NORM
	HI		HI
2	LO	ON	LO
	MAN		MAN
	NORM		NORM
	HI		HI

Intentionally left blank

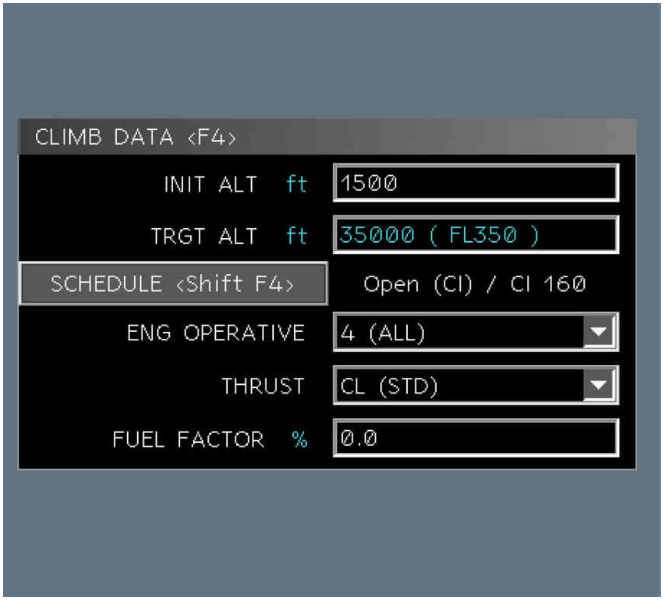
CLIMB DATA PANEL

Applicable to: ALL

The CLIMB DATA panel provides the following information:

- Initial altitude
- Target altitude
- Climb speed schedule (climb selection, specific information on the climb speed schedule, minimum rate of climb, buffet margin).
- Number of engines operative
- Thrust lever position
- Fuel factor.

CLIMB DATA Panel



INITIAL ALTITUDE

Applicable to: ALL

The initial altitude is the pressure altitude at which the computation of an initial climb or step climb begins.

TARGET ALTITUDE

Applicable to: ALL

The target altitude is the pressure altitude at which the computation should stop.
If the target altitude is above the climb ceiling in the conditions defined, the computation will end at the climb ceiling.

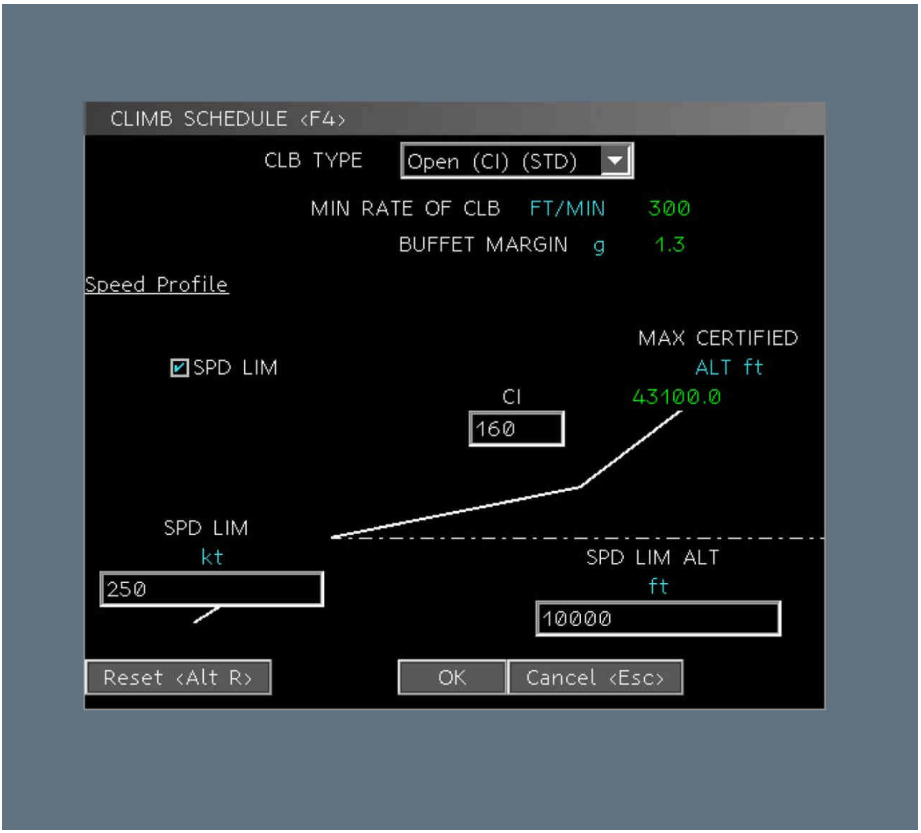
CLIMB SCHEDULE

Applicable to: ALL

The CLIMB SCHEDULE subpanel includes the following information:

- Climb selection
- Specific information on the climb speed schedule
- Minimum rate of climb
- Buffet margin.

CLIMB SCHEDULE Subpanel



CLIMB TYPE

The flight crew uses the CLB TYPE drop-down list to define the climb type.

The following climb types are available:

- Open (CI)

L2 For more information about the Open (CI) climb type, *Refer to PER-IFT-CLB-OCI General* .

L1 - Selected speeds

L2 For more information about the Selected speeds climb type, *Refer to PER-IFT-CLB-SSP General* .

L1 - Best rate

L2 For more information about the Best rate climb type, *Refer to PER-IFT-CLB-BRT General* .

L1 - Best angle

L2 For more information about the Best angle climb type, *Refer to PER-IFT-CLB-BAN General* .

L1 - Turbulence .

L2 For more information about the Turbulence climb type, *Refer to PER-IFT-CLB-TBL General* .

BUFFET MARGIN

GENERAL

Aircraft maneuverability is limited by the load factor at which buffet onset begins.
To ensure a sufficient aircraft maneuverability, a buffet margin in level flight is maintained. It is expressed as a factor of g.

L2 The load factor is defined as the ratio between lift and weight.

L1 This load factor limit is called buffet margin.

CLB

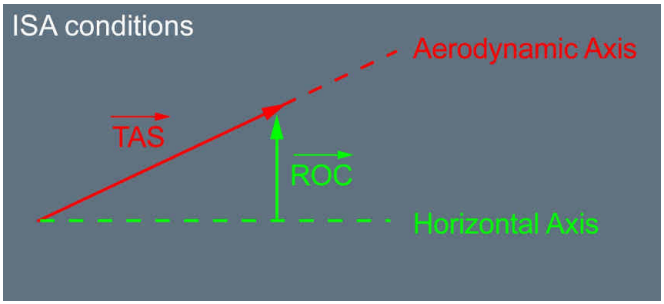
The buffet margin is generally fixed to 1.3 for all engine operations.
For the Turbulence climb type, the buffet margin is generally increased to 1.4.
The buffet margin is used to determine the buffet ceiling.

MINIMUM RATE OF CLIMB

GENERAL

In ISA conditions, the Rate Of Climb (ROC) represents the vertical component of the aircraft's speed (i.e. the vertical speed).

ROC definition



CLB

Theoretically, a climb could continue until the ROC is equal to zero. But the final part of the climb would amount to a drift up that considerably increases climb time, distance and fuel.
To prevent this, the climb is usually stopped when a minimum residual climb capability is reached, the minimum ROC.
The minimum ROC is generally fixed to 300 ft/min in normal conditions.
The target altitude may be not reachable if the residual climb capability at that level is less than the minimum ROC.

ENGINES OPERATIVE

Applicable to: ALL

GENERAL

The number of engines operative determines the thrust available to perform the climb and therefore largely impacts the climb performance and the climb strategy (e.g. climb at green dot speed after an engine failure).

CLB

The flight crew selects the number of engines operative:
- 4 (ALL), or
- 3, or
- 2.

A climb on less than 2 engines is not considered.

THRUST

Applicable to: ALL

GENERAL

The thrust available to perform the climb depends on the selected climb rating.
The standard climb rating is “Maximum Climb Thrust”, which is delivered when the thrust lever is in the CL detent.
Three "Derated Climb Thrust" levels are available (DCL1, DCL2, DCL3).
For more information about derated climb, *Refer to PER-THR-NRM-DCL Derated Climb* and *Refer to PER-THR-NRM-DCL-DCL Derated Climb Level Determination* .
In the case of an engine failure, the rating “Maximum Continuous Thrust” is mandatory.

CLB

The flight crew selects the thrust rating:
- CL (AEO), or
- CL-D01 (AEO), or
- CL-D02 (AEO), or
- CL-D03 (AEO), or
- MCT (OEI).

FUEL FACTOR

Applicable to: ALL

GENERAL

The performance factor for FMS predictions (FMS PERF FACTOR) is the sum of the Basic FMS PERF FACTOR and the Monitored Fuel Factor.

BASIC FMS PERF FACTOR

The Basic FMS PERF FACTOR correction is applied when the aircraft FMS database does not exactly fit to the aircraft model. It is published for each FMS Performance Data Base (PDB).
It results in FMS predictions consistent with the level reflected by the uncorrected IN-FLT PERF application, also called the book level.

MONITORED FUEL FACTOR

The actual airframe drag and engine performance deviate from the nominal model due to the aircraft's aging process.
The Monitored Fuel Factor is used to correct the performance book level to the actual performance level in order to permit realistic fuel predictions.
The Monitored Fuel Factor is defined as a percentage increase or decrease of the nominal Specific Range (SR) value.

IN-FLT PERF

The IN-FLT PERF fuel factor corresponds to the sum of:
- The Monitored Fuel Factor, and
- A positive performance prediction adjustment (if enabled, and at flight crew discretion).

L2 This allows the flight crew to adjust performance predictions to a drag increase due to non-quantified aerodynamic sources.

L1 When no such performance adjustment is required, the IN-FLT PERF fuel factor may thus differ from the FMS one by the Basic FMS PERF FACTOR.

Intentionally left blank

GENERAL

Applicable to: ALL

The Open (CI) climb type enables the flight crew to emulate several MFD CLB page performance predictions:

- Recommended Maximum (REC MAX) altitude
- ECON speed and Mach
- Distance to targeted altitude
- Time to targeted altitude.

Furthermore, the Open (CI) climb type provides some additional performance information, like gradient (GRDT) and vertical speed (ROC) along the flight path.

L2 This is flown in managed speed/Mach target.

L3 The Open (CI) climb type combines the use of the FMS managed speed/Mach targets with the physical model of the aircraft, whereas the FMS predictions use a simplified model of the aircraft.

COST INDEX

Applicable to: ALL

The Cost Index (CI) is defined as the ratio between Cost of Time per time unit (CT) and Cost of Fuel per mass unit (CF).

The CI value is expressed in hundreds of pounds per hour (100 lb/h).

The purpose of the CI concept is to reduce Direct Operating Costs (DOC).

L2 DOCs are made up of:

- Fixed costs
- Time-related costs, which can be expressed as CT × (trip time)
- Cost of fuel, which can be expressed as CF × (trip fuel).

SPEED PROFILE

Applicable to: ALL

GENERAL

A climb in managed speed/Mach target is generally operated using a speed profile divided into two main phases:

- An optional climb speed limit phase

L2 The climb speed limit is a speed constraint to be respected, up to a specified altitude.

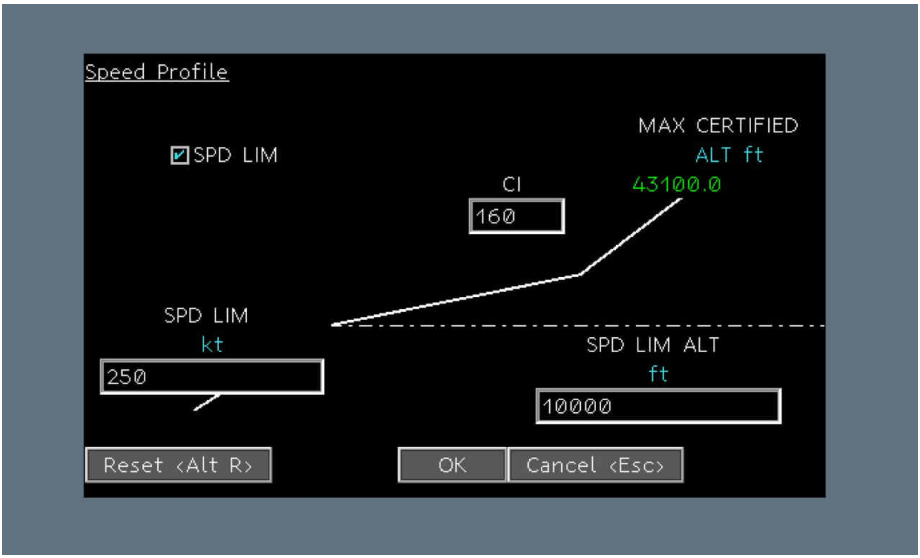
L1 - An economic climb schedule (ECON IAS / ECON Mach law).

L2 For more information about the economic climb schedule, *Refer to PER-IFT-CLB-OCI Economic Climb Schedule* .

L1 CLB

WITH A SPEED LIMIT

Speed Profile Subpanel - With a Speed Limit



The flight crew enters:

- The CI value used to manage the flight
- The climb speed limit CAS (SPD LIM)
- The climb speed limit altitude (SPD LIM ALT).

WITHOUT A SPEED LIMIT

Speed Profile Subpanel - Without a Speed Limit

The flight crew enters the CI value used to manage the flight.

ECONOMIC CLIMB SCHEDULE

Applicable to: ALL

An economic climb schedule is a predetermined IAS /Mach climb speed law depending on CI .
The ECON climb Mach is identical to the first ECON cruise Mach.

L2 The IAS phase is flown at ECON IAS function of:

- CI
- Top Of Climb (T/C) altitude
- Predicted weight at T/C .

The Mach phase is flown at ECON Mach function of:

- CI
- T/C altitude
- Predicted weight at T/C altitude
- Temperature
- Wind.

For more information about the ECON Mach, *Refer to Cruise - ECON Mach* .

GENERAL

Applicable to: ALL

The flight crew may use the Selected speeds climb type to calculate climb performance for a climb in selected speed/Mach target with a given fixed speed schedule.

SPEED PROFILE

Applicable to: ALL

GENERAL

A climb in selected speed/Mach target is generally operated using a speed profile divided into three phases (SPD LIM/SPD/MACH).
The standard climb speed profile is 250 kt/320 kt/M 0.84 with a speed constraint up to FL 100.

BELOW THE CLIMB SPEED LIMIT ALTITUDE

This climb phase is operated at constant IAS (SPD LIM).
The speed is limited by ATC and according to airspace rules.

ABOVE THE CLIMB SPEED LIMIT ALTITUDE

This climb phase is operated at a higher IAS (SPD), which is maintained up to the crossover altitude.

L2 The crossover altitude is the pressure altitude at which SPD and MACH are equal to the same TAS.
At constant IAS, TAS increases with pressure altitude.
This acceleration progressively reduces climb capability.

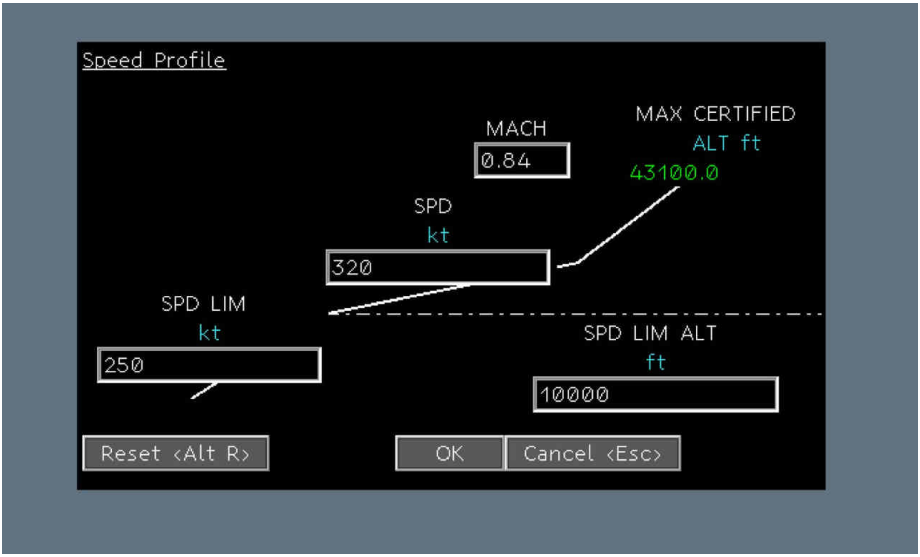
L1 ABOVE THE CROSSOVER ALTITUDE

This climb phase is operated at constant Mach (MACH) to improve the climb ceiling.

L2 At constant Mach, TAS decreases with pressure altitude.
This deceleration restores some climb capability.

L1 **CLB**

Speed Profile Subpanel



The flight crew enters:

- The climb speed limit CAS (SPD LIM)
- The climb speed limit altitude (SPD LIM ALT)
- The climb speed CAS (SPD)
- The climb speed Mach (MACH).

Intentionally left blank

GENERAL

Applicable to: ALL

The flight crew may use the Best rate climb type to calculate climb performance with the aim of reaching the targeted altitude in the shortest time.
This may be flown in selected speed/Mach target by manually setting the best rate speed on the AFS CP, computed by the IN-FLT PERF Best rate climb type.

Intentionally left blank

GENERAL

Applicable to: ALL

The flight crew may use the Best angle climb type to calculate climb performance with the aim of reaching the targeted altitude in the shortest distance.

This is flown in selected speed/Mach target by manually setting the green dot speed on the AFS CP computed by:

- The FMC based on aircraft weight, and indicated on the PFD and the MFD PERF CLB page (MAX ANGLE function), or
- The IN-FLT PERF Best angle climb type.

Intentionally left blank

GENERAL

Applicable to: ALL

The flight crew may use the Turbulence climb type to calculate climb performance for a climb in selected speed/Mach target operated through turbulence areas.

L2 Turbulence speeds are recommended when the aircraft flies in a turbulent atmosphere. They increase the margin to buffet onset, which is more likely to occur due to Angle Of Attack (AOA) variations induced by disturbances in these meteorological conditions.

L1 This is flown in selected speed/Mach target by manually setting the MAX TURB fixed IAS/Mach law on the AFS CP, computed by the FMC and indicated on the MFD PERF CLB page (MAX TURB function).

This may also be flown in selected speed/Mach target by manually setting the turbulence climb speed profile on the AFS CP, given by the IN-FLT PERF Turbulence climb type.

SPEED PROFILE

Applicable to: ALL

The recommended turbulence penetration airspeed (VRA/MRA) is between green dot and 300 kt/M 0.85.

The MAX TURB function indicated on the MFD PERF CLB page displays the maximal speed/Mach not to exceed according to this recommendation.

The IN-FLT PERF Turbulence climb type philosophy is different. It enables to make a computation from the Operator's turbulence climb speed profile.

The optimum turbulence climb speed profile in terms of margin towards buffet onset is 260 kt/300 kt/M 0.85 with a speed constraint up to FL 100.

Intentionally left blank

REC MAX ALTITUDE

Applicable to: ALL

GENERAL

The FMS Recommended Maximum (REC MAX) altitude is a precomputed value, function of the aircraft gross weight and DISA, displayed on all the PERF pages as long as all engines are operative.

L2 REC MAX altitude respects the following criteria:
- It can be flown with a speed higher than green dot speed and lower than Maximum Operating Speed/Mach (VMO/MMO)
- It can be reached with a minimum rate of climb of 300 ft/min at “Maximum Climb Thrust” rating
- It can be flown in level flight without acceleration with a rating less than “Maximum Cruise Thrust”
- It can be reached before buffeting with a margin of 0.3 g
- It is less than the maximum certified altitude.

L1 CLB

REC MAX altitude is only computed for the Open (CI) climb type.
For all engines operative, it corresponds to the REC MAX altitude displayed on the MFD.

CLIMB CEILING

Applicable to: ALL

GENERAL

The climb ceiling is the pressure altitude at which the calculated Rate of Climb (ROC) is equal to the minimum ROC .

L2 For more information about the minimum ROC , *Refer to PER-IFT-CLB-CBD-CSH Minimum Rate of Climb* .

L1 CLB

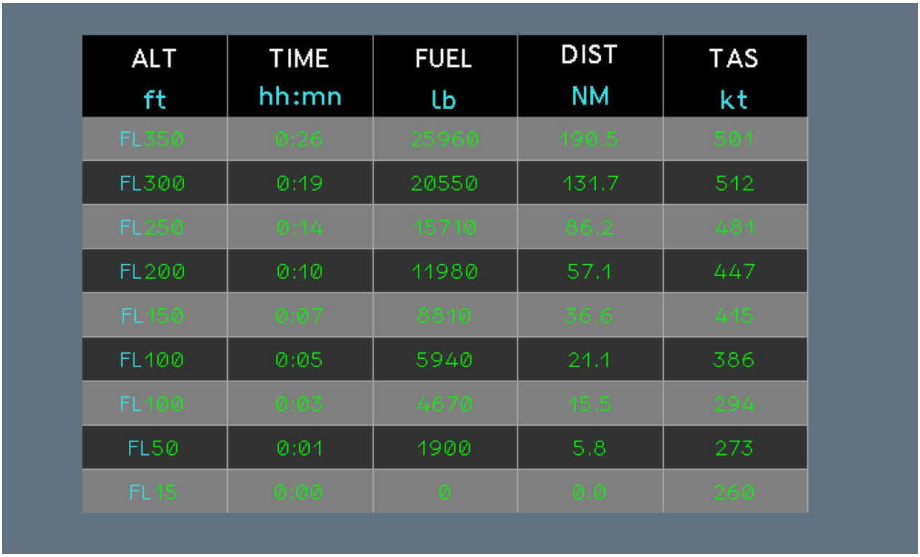
The climb ceiling is calculated for the following climb types:
- Selected speeds
- Best rate
- Best angle
- Turbulence .

BASIC RESULTS PANEL

Applicable to: ALL

The basic RESULTS panel provides the essential information for the climb via a typical climb table.

Basic RESULTS Table



ALT ft	TIME hh:mn	FUEL lb	DIST NM	TAS kt
FL350	0:26	25960	190.5	501
FL300	0:19	20550	131.7	512
FL250	0:14	15710	86.2	481
FL200	0:10	11980	57.1	447
FL150	0:07	8810	36.6	415
FL100	0:05	5940	21.1	386
FL100	0:03	4670	15.5	294
FL50	0:01	1900	5.8	273
FL15	0:00	0	0.0	260

ALT

This column displays the altitude from the initial pressure altitude to the target pressure altitude (or the final pressure altitude limited by the minimum Rate of Climb (ROC) value) with a step of 5 000 ft.

TIME

This column displays the time elapsed from the initial pressure altitude to each intermediate pressure altitude.

FUEL

This column displays the fuel burnt from the initial pressure altitude to each intermediate pressure altitude.

DIST

This column displays the ground distance covered from the initial pressure altitude to each intermediate pressure altitude.

TAS

This column displays the instantaneous True Air Speed (TAS) at each intermediate pressure altitude.

TABLE RESULTS SUBPANEL

Applicable to: ALL

The TABLE RESULTS subpanel provides the detailed information for the climb. The parameters displayed depend on the Operator customization.
In addition to the basic table, the detailed table may include:

ALTG

This column displays the geometric altitude corresponding to each intermediate pressure altitude.

WGHT

This column displays the aircraft weight at each intermediate pressure altitude.

CAS

This column displays the instantaneous Calibrated Air Speed (CAS) at each intermediate pressure altitude.

MACH

This column displays the instantaneous Mach number at each intermediate pressure altitude.

THR

This column displays the instantaneous THR at each intermediate pressure altitude.
L2 The THR value indicates the thrust used. It is shown as a % of the available thrust.

Assuming that the thrust achieved in windmilling is close to zero, the available thrust is the ratio of the actual thrust calculated from engine parameters to:
- The thrust achieved with TO thrust rating and bleeds OFF for Takeoff and Taxi
- The thrust achieved with GA thrust rating and bleeds OFF for all other flight phases (Climb, Cruise, Descent, Holding).

L1 **GRDT**

This column displays the instantaneous climb gradient at each intermediate pressure altitude.
L2 The climb gradient represents the angle between the horizontal axis and the aerodynamic axis defined by the speed direction.

L1 **RATE**

This column displays the instantaneous Rate Of Climb (ROC) at each intermediate pressure altitude.
L2 In ISA conditions, ROC represents the vertical component of the speed.
In ISA conditions, ROC = TAS x sin (GRDT) ~ TAS x GRDT.

L1 WITH TAKEOFF

The flight crew can use the "With Takeoff" tick box to take into account the time allowance and the distance allowance for the takeoff phase of the climb:

- When the "With Takeoff" tick box is unticked, IN-FLT PERF computes the time and the distance results from the INIT ALT entered by the flight crew in the CLIMB DATA panel
- When the "With Takeoff" tick box is ticked, IN-FLT PERF computes the time and the distance results from the takeoff point of the aircraft.

For more information about the "With Takeoff" tick box, *Refer to PER-IFT-CLB-CBR GRAPH RESULTS Subpanel* .

GRAPH RESULTS SUBPANEL

Applicable to: ALL

The flight crew can plot climb parameters versus each other using the GRAPH RESULTS subpanel. The possible parameters depend on the Operator customization of the TABLE RESULTS.
Specific values can be read from the graph using the cross-hairs.
The flight crew can use the "With Takeoff" tick box to take into account the time allowance and the distance allowance for the takeoff phase of the climb. When the "With Takeoff" tick box is ticked, the origin of the graph is moved to take into account the new initial conditions.

GRADIENT

When ALT is plotted against DIST, three fixed gradients are displayed:
- 3 %
- 5 %
- 7.5 %.

These fixed gradients are also displayed when GRDT is plotted against any parameter.

WITHOUT TAKEOFF

When the "With Takeoff" tick box is unticked:
- The origin of the aircraft trajectory (cyan curve) is:
  - DIST = 0
  - ALT = INIT ALT entered by the flight crew in the CLIMB DATA panel.
- The origin of the gradient graph (yellow curve) is:
  - DIST = 0
  - ALT = 35 ft.

WITH TAKEOFF

When the "With Takeoff" tick box is ticked:
- The origin of the aircraft trajectory (cyan curve) is:
  - DIST = Takeoff distance allowance
  - ALT = INIT ALT entered by the flight crew in the CLIMB DATA panel.
- The origin of the gradient graph (yellow curve) is:
  - DIST = 1/3 of the takeoff distance allowance
  - ALT = 35 ft.

RATE OF CLIMB

When ALT is plotted against TIME, three fixed ROCs are displayed:
- 1 000 ft/min
- 1 500 ft/min
- 2 000 ft/min.

These ROCs are also displayed when RATE is plotted against any parameter.

WITHOUT TAKEOFF

When the "With Takeoff" tick box is unticked:
- The origin of the aircraft trajectory (cyan curve) is:
  - TIME = 0
  - ALT = INIT ALT entered by the flight crew in the CLIMB DATA panel.
- The origin of the gradient graph (yellow curve) is:
  - TIME = 0
  - ALT = 35 ft.

WITH TAKEOFF

When the "With Takeoff" tick box is ticked:
- The origin of the aircraft trajectory (cyan curve) is:
  - TIME = Takeoff time allowance
  - ALT = INIT ALT entered by the flight crew in the CLIMB DATA panel.
- The origin of the gradient graph (yellow curve) is:
  - TIME = 2/3 of the takeoff time allowance
  - ALT = 35 ft.

Intentionally left blank

IN-FLT PERF APPLICATION - CRZ MODULE

Applicable to: ALL

GENERAL

The cruise phase starts at the Top of Climb (T/C) and ends at the Top of Descent (T/D).

CRZ

The IN-FLT PERF application is made of 6 modules (CLB, CRZ, DES, HLD, PLAN and ATMO).

The CRZ module enables the flight crew to obtain current and predicted cruise performance data for:

- Given meteorological conditions
- A given aircraft configuration including non standard ones (engines out, landing gear down)
- Given speed or cost index.

The main results of this module are:

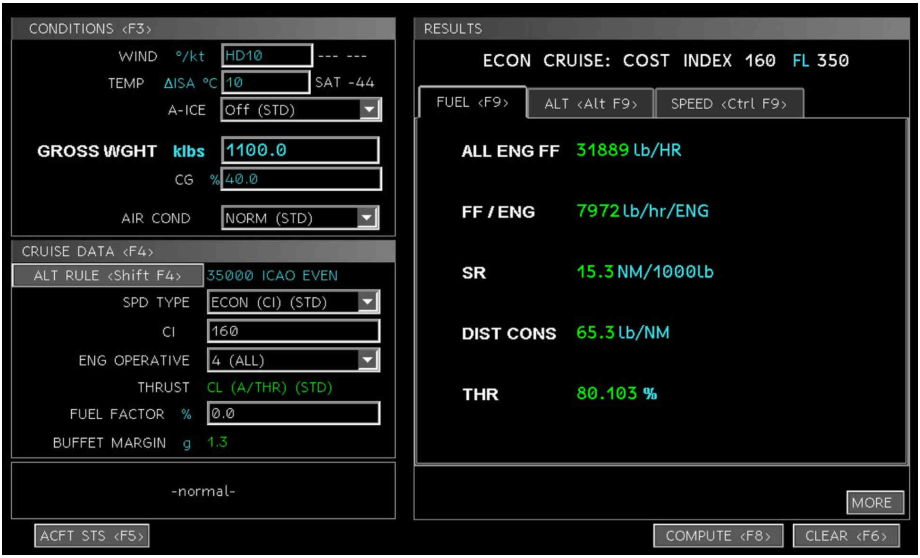
- Fuel results: the Fuel Flow (FF), the Specific Range (SR), the THR
- Altitude results: the maximum altitude, the optimum altitude, the specific range equivalence
- Speed results: the Mach, the Calibrated Air Speed (CAS), the True Air Speed (TAS), the N1.

Intentionally left blank

CRZ MODULE INTERFACE

Applicable to: ALL

IN-FLT PERF CRZ Module Interface



CONDITIONS

The flight crew can define the current outside conditions and the aircraft configuration.
For more information about the CONDITIONS panel, *Refer to PER-IFT-CRZ-CDT CONDITIONS Panel* .

CRUISE DATA

The flight crew can define the data of the cruise phase.
For more information about the CRUISE DATA panel, *Refer to PER-IFT-CRZ-CRD CRUISE DATA Panel* .

AIRCRAFT STATUS

The flight crew can select CDL items and non standard configuration items.
For more information about the AIRCRAFT STATUS panel, *Refer to PER-IFT-ACS AIRCRAFT STATUS Panel* .

RESULTS

The RESULTS panel displays the essential information for the cruise phase:

- Fuel
- Altitude
- Speed.

For more information about the RESULTS panel, refer to Cruise Results.

CONDITIONS PANEL

Applicable to: ALL

The CONDITIONS panel provides the following information:

- Wind
- Heading
- Temperature (Δ ISA)
- Anti-ice
- Gross weight
- CG
- Airflow.

CONDITIONS Panel

WIND

Applicable to: ALL

GENERAL

The wind affects:
- The Ground Speed (GS)
- The Specific Range (SR)
- The ECON and LRC Mach.

A tailwind will induce:
- An increase in SR
- A decrease in ECON and LRC Mach.

On the contrary, a headwind will induce:
- A decrease in SR
- An increase in ECON and LRC Mach.

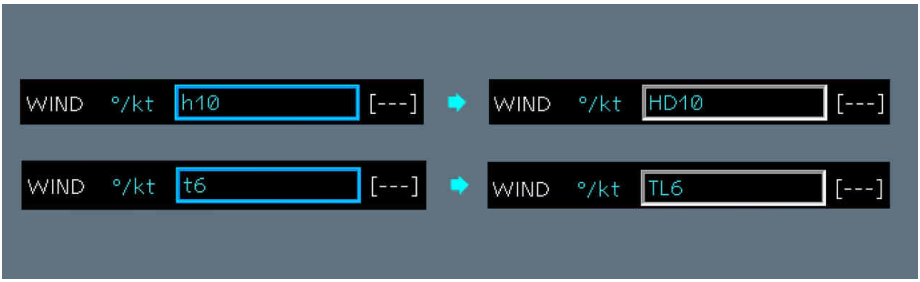
CRZ

There are two ways to define wind values:
- Longitudinal Speed Component
- Direction/Speed Combination.

LONGITUDINAL SPEED COMPONENT

The flight crew enters the longitudinal component with:
- H or HD followed by the headwind speed (e.g. H10 or HD5), or
- T or TL followed by the tailwind speed (e.g. T6 or TL8).

Wind Values Input - Longitudinal Speed Component



DIRECTION/SPEED COMBINATION

The flight crew enters the wind direction and the wind speed.
The entry is projected along the heading and perpendicular to the heading.

The longitudinal projection follows the same display rules as the speed entry.

IN-FLT PERF displays the crosswind as:
- R, if the wind comes from the right, or
- L, if the wind comes from the left.

Wind Values Input - Direction/Speed Combination

HEADING

Applicable to: ALL

GENERAL

The heading defines the axis on which the wind is projected.

CRZ

The IN-FLT PERF heading and wind direction have to be both entered in either magnetic or true north.
The HDG field is only displayed if a wind has been entered in a combination of a direction and a speed.

L2 For more information about the wind, *Refer to Cruise - Wind* .

TEMPERATURE

Applicable to: ALL

GENERAL

An increase in temperature (SAT or ΔISA) leads to:

- A higher true altitude at fixed indicated altitude
- A higher True Air Speed (TAS) for the same Calibrated Air Speed (CAS) or Mach

L2 At fixed CAS, TAS is inversely proportional to air density, which decreases with temperature. At fixed Mach, TAS increases with temperature.

L1 - A higher required net thrust to fly this TAS.

L2 The net thrust is the difference between the gross thrust and the capturing drag. It is the thrust necessary to maintain the level flight.

L1 Thus, when temperature increases:

- Fuel Flow (FF) increases
- Specific Range (SR) decreases

L2 The increase in Ground Speed (GS) does not offset the increment in FF.

L1 - THR increases

L2 The maximum available thrust decreases with temperature, and the required net thrust increases.

L1 - The Maximum Cruise Altitude (MAX CRZ ALT) decreases

L2 The applicable thrust limit is reached at a lower altitude.

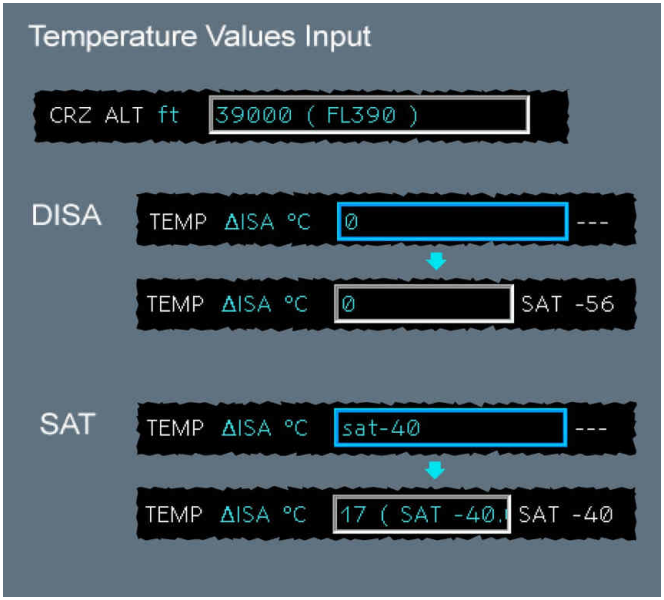
L1 - The Optimum Altitude (OPT ALT) stays roughly the same

L2 OPT ALT is the result of a comparison of SR at different altitudes. These SR values vary with temperature in the same way at all altitudes.

L1 - ECON and LRC Mach decrease.

CRZ

Temperature Values Input



The TEMP field corresponds to a deviation from ISA law (ΔISA).

The flight crew can enter a temperature as:

- A ΔISA, or
- A Static Air Temperature (SAT) at cruise altitude, which is automatically converted into a ΔISA.

ANTI-ICE

Applicable to: ALL

GENERAL

In cruise, anti-ice increases engine bleed.

L2 The net thrust (which is the thrust necessary to maintain the level flight) stays the same. But, the increased bleed flow leads to an increased Fuel Flow (FF) to generate this thrust.

L1 Thus, in the case of ENG and/or WING anti-ice:

- FF increases
- Specific Range (SR) decreases
- THR increases
- The Maximum Cruise Altitude (MAX CRZ ALT) decreases

L2 The applicable thrust limit is reached at a lower altitude.

L1 - The Optimum Altitude (OPT ALT) stays roughly the same

L2 OPT ALT is the result of a comparison of SR at different altitudes. These SR values vary with anti-ice in the same way at all altitudes.

L1 - LRC Mach slightly decreases
- ECON Mach remains the same.

L2 The FMS model does not consider bleed variations.

L1 IN-FLT PERF

IN-FLT PERF has four anti-ice options:

- Off
- Engine
- Total
- Severe Icing.

  The flight crew may use the Severe Icing option to assess the impact of ice accretion on fuel consumption and ceilings.

GROSS WEIGHT

Applicable to: ALL

GENERAL

L2 When the weight increases, the lift must be increased to maintain the altitude. As a result, the drag increases. So, the net thrust must be increased at fixed CAS or Mach.

L1 At a fixed pressure altitude, any decrease in weight, due to fuel burn off for example, leads to:
- A lower Fuel Flow (FF)
- A higher Specific Range (SR).

L2 The SR is inversely proportional to FF.

L1 - A lower THR

L2 The required net thrust decreases.

L1 - A higher Maximum Cruise Altitude (MAX CRZ ALT)
- A higher Optimum Altitude (OPT ALT)
- A lower ECON and LRC Mach.

CRZ

The flight crew enters the current aircraft weight at start of cruise calculation.
This gross weight (GROSS WGHT field) must be between the Operating Empty Weight (OEW) and the Maximum Design Takeoff Weight (MTOW).

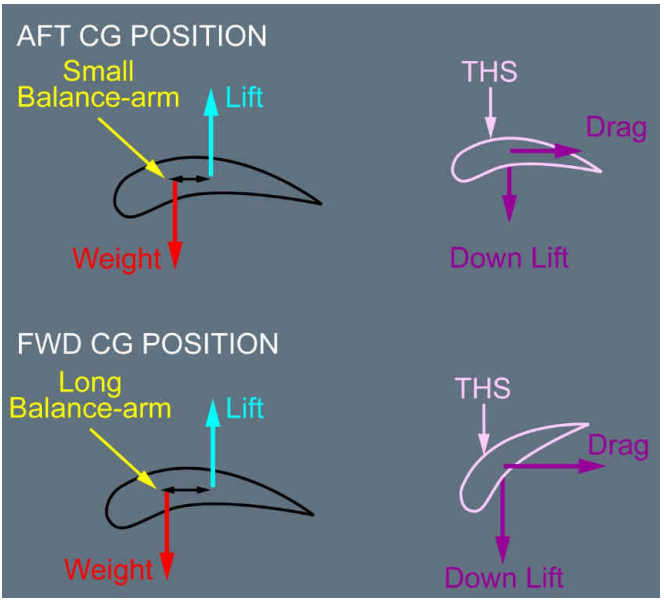
CG

Applicable to: ALL

GENERAL

The Center of Gravity (CG) position impacts the forces applied on the aircraft. As a result, it impacts aircraft performance.

CG Position



L2 In order to keep the aircraft level, the Trimmable Horizontal Stabilizer (THS) creates a downward force that counters the pitch down moment due to the distance between the center of lift and the center of gravity. The larger this lever arm, the higher the down lift that must be generated by the THS, and the higher the drag.

L1 **IN-FLT PERF**

The CG field is expressed in % of the Mean Aerodynamic Chord (MAC).

AIRFLOW

Applicable to: ALL

GENERAL

In cruise, high airflow increases engine bleed.

L2 The net thrust (which is the thrust necessary to maintain the level flight) stays the same. But, the increased bleed flow leads to an increased Fuel Flow (FF) to generate this thrust.

L1 Thus, in the case of an increase in airflow:

- FF increases
- Specific Range (SR) decreases
- THR increases
- The Maximum Cruise Altitude (MAX CRZ ALT) decreases

L2 The applicable thrust limit is reached at a lower altitude.

L1 - The Optimum Altitude (OPT ALT) stays roughly the same

L2 OPT ALT is the result of a comparison of SR at different altitudes. These SR values vary with airflow in the same way at all altitudes.

L1 - LRC Mach decreases
- ECON Mach remains the same.

L2 The FMS model does not consider bleed variations.

L1 IN-FLT PERF

IN-FLT PERF has five airflow options:

- OFF
- LO
- MAN
- NORM
- HI.

IMPACT OF FWD CARGO COOLING

When FWD cargo cooling is active, the airflow automatically increases, and so the engine bleed.
The IN-FLT PERF airflow settings reflect the engine bleed with FWD cargo cooling OFF.
The flight crew applies the following equivalences to obtain an engine bleed that considers the effect of FWD cargo cooling:

ENG OPERATIVE	AIR FLOW Selector	FWD Cargo Cooling	Select IN-FLT PERF setting
4	LO	ON	MAN
	MAN		HI
	NORM		HI
	HI		HI
3	LO	ON	MAN
	MAN		MAN
	NORM		NORM
	HI		HI
2	LO	ON	LO
	MAN		MAN
	NORM		NORM
	HI		HI

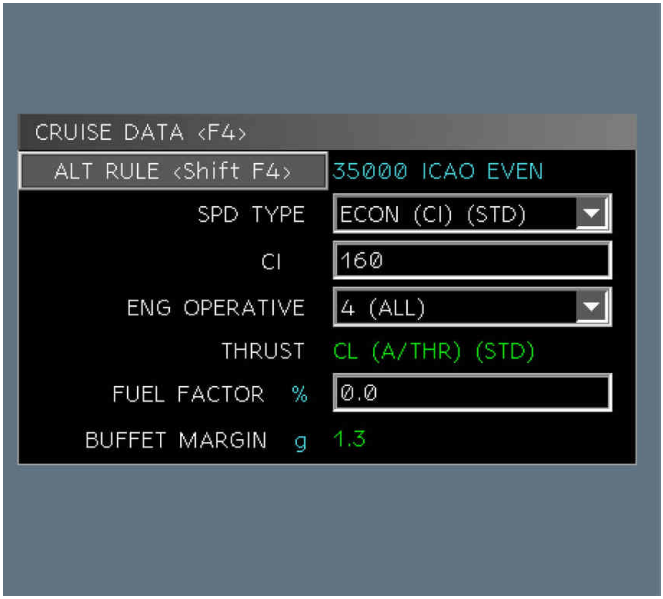
CRUISE DATA PANEL

Applicable to: ALL

The CRUISE DATA panel provides the following information:

- Altitude profile (cruise altitude, altitude rule)
- Speed type
- Engines operative
- Thrust lever position
- Fuel factor
- Buffet margin.

CRUISE DATA Panel



ALTITUDE PROFILE

Applicable to: ALL

The ALT RULE subpanel provides the following information:

- Cruise altitude
- Altitude rule.

ALT RULE Subpanel

CRUISE ALTITUDE - GENERAL

THRUST AND FUEL FLOW

In level flight, the thrust is inversely proportional to the lift-to-drag ratio.
At fixed Mach, the lift-to-drag ratio increases with altitude up to the optimum altitude. Above this optimum altitude, it decreases.

Altitude below the optimum altitude

A higher pressure altitude results in:
- A lower net thrust
  The net thrust is the thrust necessary to maintain the level flight.
- A lower Fuel Flow (FF).

Altitude above the optimum altitude

A higher pressure altitude results in:
- A higher net thrust
- A higher FF.

THR

Altitude below the optimum altitude

Below the optimum altitude, the maximum available thrust decreases with pressure altitude at a higher rate than the decrease in required net thrust.
So, THR increases.

Altitude above the optimum altitude

Above the optimum altitude, the maximum available thrust decreases with pressure altitude, and the required net thrust increases.
So, THR increases.

TRUE AIR SPEED

At fixed Mach, the True Air Speed (TAS) is proportional to SAT, which:
- Decreases with altitude below the tropopause
- Remains constant above the tropopause.

Altitude below the tropopause

A higher pressure altitude results in:
- A lower TAS.

Altitude above the tropopause

A higher pressure altitude results in:
- No change in TAS.

SPECIFIC RANGE

The main influence on the Specific Range (SR) is the Lift to Drag ratio. At the optimum altitude defined as the pressure altitude for which SR is maximum, the Lift to Drag ratio is maximum as well.

Altitude below the optimum altitude

A higher pressure altitude results in:
- A higher SR.

Altitude above the optimum altitude

A higher pressure altitude results in:
- A lower SR.

ECON AND LRC MACH

ECON and LRC Mach increase with pressure altitude.

CRUISE ALTITUDE - CRZ

The flight crew enters the current pressure altitude.

ALTITUDE RULES

GENERAL

The altitude rule defines which flight levels may be used in a given region, depending on the aircraft heading.

IN-FLT PERF

IN-FLT PERF provides the following altitude rules:

- ICAO EVEN
- ICAO ODD
- RVSM EVEN
- RVSM ODD
- CHINA 180°-359° (metric)
- CHINA 360°-179° (metric)
- RUSSIA 180°-359° (metric)
- RUSSIA 360°-179° (metric).

The field defaults to the first applicable altitude rule identified from the above list, depending on the selected pressure altitude.

SPEED TYPE

Applicable to: ALL

The flight crew uses the SPD TYPE drop-down list to define the cruise type.

The following cruise types are available:

- ECON (CI)

L2 For more information about the ECON (CI) cruise type, *Refer to PER-IFT-CRZ-ECI General* .

L1 - Fixed Speed

L2 For more information about the Fixed Speed cruise type, *Refer to PER-IFT-CRZ-FSP General* .

L1 - LRC Speed

L2 For more information about the LRC Speed cruise type, *Refer to PER-IFT-CRZ-LRC General* .

L1 - Green Dot Speed

L2 For more information about the Green Dot Speed cruise type, *Refer to PER-IFT-CRZ-GDS General* .

L1 - Turbulence Speed

L2 For more information about the Turbulence Speed cruise type, *Refer to PER-IFT-CRZ-TBS General* .

L1 - Maximum Speed

L2 For more information about the Maximum Speed cruise type, *Refer to PER-IFT-CRZ-MSP General* .

ENGINES OPERATIVE

Applicable to: ALL

GENERAL

The number of engines operative determines the thrust available to perform the cruise and therefore largely impacts the cruise performance and the type of cruise (e.g. cruise at LRC speed after an engine failure).

CRZ

The flight crew selects the number of engines operative:

- 4 (ALL), or
- 3, or
- 2.

THRUST

Applicable to: ALL

GENERAL

The thrust available to perform the cruise depends on the selected cruise rating.
The standard cruise thrust limit is the “Maximum Cruise Thrust” which is delivered when the thrust lever is in the CL detent.
However, in the case of an engine failure, the thrust rating “Maximum Continuous Thrust” is mandatory.

L2 For more information, refer to Thrust Ratings.

L1 CRZ

The thrust rating is automatically selected, depending on the number of engines operative:
- CL (A/THR), if AEO
- MCT (A/THR), if OEI or TEI.

FUEL FACTOR

Applicable to: ALL

GENERAL

The performance factor for FMS predictions (FMS PERF FACTOR) is the sum of the Basic FMS PERF FACTOR and the Monitored Fuel Factor.

BASIC FMS PERF FACTOR

The Basic FMS PERF FACTOR correction is applied when the aircraft FMS database does not exactly fit to the aircraft model. It is published for each FMS Performance Data Base (PDB).
It results in FMS predictions consistent with the level reflected by the uncorrected IN-FLT PERF application, also called the book level.

MONITORED FUEL FACTOR

The actual airframe drag and engine performance deviate from the nominal model due to the aircraft's aging process.
The Monitored Fuel Factor is used to correct the performance book level to the actual performance level in order to permit realistic fuel predictions.
The Monitored Fuel Factor is defined as a percentage increase or decrease of the nominal Specific Range (SR) value.

IN-FLT PERF

The IN-FLT PERF fuel factor corresponds to the sum of:
- The Monitored Fuel Factor, and
- A positive performance prediction adjustment (if enabled, and at flight crew discretion).

L2 This allows the flight crew to adjust performance predictions to a drag increase due to non-quantified aerodynamic sources.

L1 When no such performance adjustment is required, the IN-FLT PERF fuel factor may thus differ from the FMS one by the Basic FMS PERF FACTOR.

BUFFET MARGIN

Applicable to: ALL

GENERAL

Aircraft maneuverability is limited by the load factor at which buffet onset begins.
To ensure a sufficient aircraft maneuverability, a buffet margin in level flight is maintained. It is expressed as a factor of g.

L2 The load factor is defined as the ratio between lift and weight.

L1 This load factor limit is called buffet margin.

CRZ

The buffet margin is generally fixed to 1.3 for all engine operations.
For the Turbulence cruise type, the buffet margin is generally increased to 1.4.
The buffet margin is used to determine the buffet ceiling.

Intentionally left blank

GENERAL

Applicable to: ALL

The ECON (CI) cruise type enables the flight crew to emulate several MFD CRZ page performance predictions:

- Recommended Maximum (REC MAX) altitude
- Optimum Altitude (OPT ALT)
- ECON Mach.

Moreover, the ECON (CI) cruise type provides current and predicted performance information.

L2 This is flown in managed speed/Mach target.

L3 The ECON (CI) cruise type combines the use of the FMS managed speed/Mach targets with the physical model of the aircraft, whereas the FMS predictions use a simplified model of the aircraft.

COST INDEX

Applicable to: ALL

The Cost Index (CI) is defined as the ratio between Cost of Time per time unit (CT) and Cost of Fuel per mass unit (CF).
The CI value is expressed in hundreds of pounds per hour (100 lb/h).
The purpose of the CI concept is to reduce Direct Operating Costs (DOC).

L2 DOCs are made up of:

- Fixed costs
- Time-related costs, which can be expressed as CT × (trip time)
- Cost of fuel, which can be expressed as CF × (trip fuel).

ECON MACH

Applicable to: ALL

For a given CI, ECON Mach is defined as the Mach for which DOCs are minimum.

The ECON Mach is a function of:

- CI

L2 The ECON Mach increases when CI increases.

L1 - Cruise altitude

- Weight

L2 The ECON Mach increases when weight increases.

L1 - Temperature

L2 The ECON Mach decreases when temperature increases.

L1 - Wind.

L2 The ECON Mach increases when headwind increases.

The extreme ECON Mach values are:

- CI = 0, minimum fuel mode, if fuel is expensive
  ECON Mach = Mach of Maximum Range
- CI = 999, minimum time mode, if time is much more important than the cost of fuel
  ECON Mach = (MMO – 0.015) or (VMO – 10 kt).
  The use of CI = 999 induces a disproportionate increase in fuel consumption to permit flight at maximum managed speed.

COST INDEX LONG RANGE

Applicable to: ALL

The Cost Index Long Range (CI_{LRC}) is defined as the CI value which approximates the Long Range Cruise (LRC) speed with all engines operative.

L2 CI_{LRC} is determined in such a way that, for a cruise altitude equal to the FMS OPT ALT ± 10 000 ft, the SR at CI_{LRC} allows ± 1% variation around the SR at LRC speed with all engines operative.

L1 CI_{LRC} = 210.

GENERAL

Applicable to: ALL

The flight crew may use the Fixed Speed cruise type to obtain current and predicted cruise performance data for a cruise in selected speed/Mach target and at fixed Mach or a fixed Calibrated Air Speed (CAS).

SPEED

Applicable to: ALL

The speed is either a Mach or a CAS.
The standard cruise Mach is M 0.85.

Intentionally left blank

GENERAL

Applicable to: ALL

The flight crew may use the LRC Speed cruise type to obtain current and predicted cruise performance data for a cruise at Long Range Cruise (LRC) speed.

This is flown in selected speed/Mach target by manually setting the LRC speed on the AFS CP, computed by:

- The FMC based on aircraft weight, and indicated on the MFD PERF CRZ page (LRC function), or
- The IN-FLT PERF LRC Speed cruise type.

LONG RANGE CRUISE SPEED

Applicable to: ALL

The Long Range Cruise (LRC) speed is defined as the Mach for which the Specific Range (SR) is equal to 99 % of the maximum SR.

L2 The purpose of LRC speed is to achieve a significant increase in cruise speed versus the Mach of maximum range for a relatively moderate cost in terms of fuel.

L1 The LRC Mach depends on:

- Cruise altitude

L2 The LRC Mach increases when pressure altitude increases.

L1 - Weight

L2 The LRC Mach increases when weight increases.

L1 - Temperature

L2 The LRC Mach decreases when temperature increases.

L1 - Wind

L2 The LRC Mach increases when headwind increases.

L1 - Airflow and anti-ice.

L2 The LRC Mach slightly decreases when bleeds increases.

L1 The standard cruise Mach (M 0.85) corresponds to the LRC Mach at optimum altitude, ISA conditions, without wind, airflow NORM and anti-ice OFF, for a wide range of weights.

Intentionally left blank

GENERAL

Applicable to: ALL

The flight crew may use the Green Dot Speed cruise type to obtain current and predicted cruise performance data for a cruise at green dot speed.

This is flown in selected speed/Mach target by manually setting the green dot speed on the AFS CP computed by:

- The FMC based on aircraft weight, and indicated on the PFD, or
- The IN-FLT PERF Green Dot Speed cruise type.

Intentionally left blank

GENERAL

Applicable to: ALL

The flight crew may use the Turbulence Speed cruise type to obtain current and predicted cruise performance data for a cruise operated through turbulence areas.

L2 Turbulence speeds are recommended when the aircraft flies in a turbulent atmosphere. They increase the margin to buffet onset, which is more likely to occur due to Angle Of Attack (AOA) variations induced by disturbances in these meteorological conditions.

L1 This is flown in selected speed/Mach target by manually setting the VRA or MRA on the AFS CP, computed by the FMC and indicated on the MFD PERF CRZ page (MAX TURB function).
This may also be flown in selected speed/Mach target by manually setting the VRA or MRA on the AFS CP, given by the IN-FLT PERF Turbulence Speed cruise type.

TURBULENCE SPEED

Applicable to: ALL

The recommended turbulence penetration airspeed (VRA/MRA) is between green dot and 300 kt/M 0.85.
The MAX TURB function indicated on the MFD PERF CRZ page displays the maximal speed/Mach not to exceed according to this recommendation.
The IN-FLT PERF Turbulence Speed cruise type philosophy is different. It enables to make a computation from the Operator's turbulence speed.
The optimum turbulence speed in terms of margin towards buffet onset is M 0.85.

Note: When the flight crew enters a cruise altitude below the Crossover Altitude, the IN-FLT PERF Turbulence Speed computation fails.

Intentionally left blank

GENERAL

Applicable to: ALL

The flight crew may use the Maximum Speed cruise type to obtain current cruise performance data for a cruise at maximum True Air Speed (TAS), in order to manage a medical emergency or a delay.

The maximum speed is either:
- The Maximum Operating Mach (MMO), or
- The Maximum Operating Speed (VMO), or
- The speed limited by the available thrust.

This is flown in selected speed/Mach target by manually setting the maximum speed on the AFS CP, computed by the IN-FLT PERF Maximum Speed cruise type.

The philosophy of the Maximum Speed cruise type is:
- To present performance data calculated at current altitude and maximum speed
- To compare these data versus optimum altitude ones.

L2 The optimum altitude at maximum speed is defined as the altitude for which TAS is maximum.

L1 It is recommended to prefer flying at CI=999, in order to increase the fuel efficiency with a limited speed penalty and avoid speed excursions.

Intentionally left blank

Fuel

FUEL FLOW

Applicable to: ALL

GENERAL

The Fuel Flow (FF) is defined as the fuel consumption per time unit.

CRZ

The FUEL subpanel displays:
- ALL ENG FF: The total FF in current conditions
- FF / ENG: The FF per engine in current conditions.

The flight crew may crosscheck the IN-FLT PERF FFs with:
- The ECAM SD ENGINE page for FF / ENG
- The ECAM SD FUEL page for ALL ENG FF
- The ECAM SD CRUISE page for FF / ENG.

SPECIFIC RANGE

Applicable to: ALL

GENERAL

The Specific Range (SR) is the distance covered per fuel mass unit burnt.
SR is defined as the ratio between the Ground Speed (GS) and FF.

CRZ

The FUEL subpanel displays the SR in current conditions.

DISTANCE CONSUMPTION

Applicable to: ALL

GENERAL

The distance consumption is the fuel consumption per distance unit.
This is defined as the ratio between FF and the Ground Speed (GS).

CRZ

The FUEL subpanel displays the distance consumption in current conditions.

THR

Applicable to: ALL

GENERAL

The THR value indicates the thrust used. It is shown as a % of the available thrust.

Assuming that the thrust achieved in windmilling is close to zero, the available thrust is the ratio of the actual thrust calculated from engine parameters to:

- The thrust achieved with TO thrust rating and bleeds OFF for Takeoff and Taxi
- The thrust achieved with GA thrust rating and bleeds OFF for all other flight phases (Climb, Cruise, Descent, Holding).

CRZ

The FUEL subpanel shows the THR in current conditions.
The flight crew may crosscheck the IN-FLT PERF THR with the ECAM EWD ENGINE page one.

Altitude

REC MAX ALTITUDE

Applicable to: ALL

GENERAL

The FMS Recommended Maximum (REC MAX) altitude is a precomputed value, function of the aircraft gross weight and DISA , displayed on all the PERF pages as long as all engines are operative.

L2 REC MAX altitude respects the following criteria:

- It can be flown with a speed higher than green dot speed and lower than Maximum Operating Speed/Mach (VMO / MMO)
- It can be reached with a minimum rate of climb of 300 ft/min at “Maximum Climb Thrust” rating
- It can be flown in level flight without acceleration with a rating less than “Maximum Cruise Thrust”
- It can be reached before buffeting with a margin of 0.3 g
- It is less than the maximum certified altitude.

L1 **CRZ**

REC MAX ALT

REC MAX altitude is only computed for the ECON (CI) cruise type.
For all engines operative, it corresponds to the REC MAX altitude displayed on the MFD , provided that TROPO is defaulted to 36 090 ft on the FMS - INIT page.
For more information about the FMS tropopause, *Refer to DSC-22-FMS-20-30-22FMS5020M INIT page* .

EO MAX ALTITUDE

Applicable to: ALL

GENERAL

The FMS long range cruise Engine Out Maximum (EO MAX) altitude is a precomputed value, function of the aircraft gross weight and DISA, displayed on all the PERF pages if at least one engine is inoperative.

L2 EO MAX altitude respects the following criteria:

- It can be flown with long range cruise speed
- It can be held in level flight with:
  - The operating engine(s) at “Maximum Continuous Thrust” rating
  - The external failed engine in windmilling
  - Anti-ice OFF
- It can be reached before buffeting with a margin of 0.3 g
- It is less than the maximum certified altitude.

L1 **CRZ**

EO MAX altitude is only computed for the ECON (CI) cruise type.
For OEI or TEI, it corresponds to the EO MAX altitude displayed on the MFD.

MAX ALT

Applicable to: ALL

MAXIMUM ALT

The Maximum Altitude (MAX ALT) definition depends on the cruise type.

FIXED SPEED, TURBULENCE SPEED

MAX ALT is defined as the minimum of:
- The Maximum Cruise Altitude (MAX CRZ ALT)
- The buffet ceiling.

When the flight crew selects a Non Standard Configuration (NSC) item with an associated maximum altitude, MAX ALT computed and displayed by IN-FLT PERF is limited by the maximum altitude of the NSC item.

LRC SPEED, GREEN DOT SPEED

MAX ALT is equal to MAX CRZ ALT.
When the flight crew selects a Non Standard Configuration (NSC) item with an associated maximum altitude, MAX ALT computed and displayed by IN-FLT PERF is limited by the maximum altitude of the NSC item.

MAX CRZ ALT

Applicable to: ALL

GENERAL

The Maximum Cruise Altitude (MAX CRZ ALT) is defined as the maximum altitude which can be flown in level flight without acceleration at the applicable thrust rating.
It must be less than the Maximum Certified Altitude.

CRZ

MAX CRZ ALT is calculated for the following cruise types:

- Fixed Speed
- LRC Speed
- Green Dot Speed
- Turbulence Speed.

BUFFET CEILING

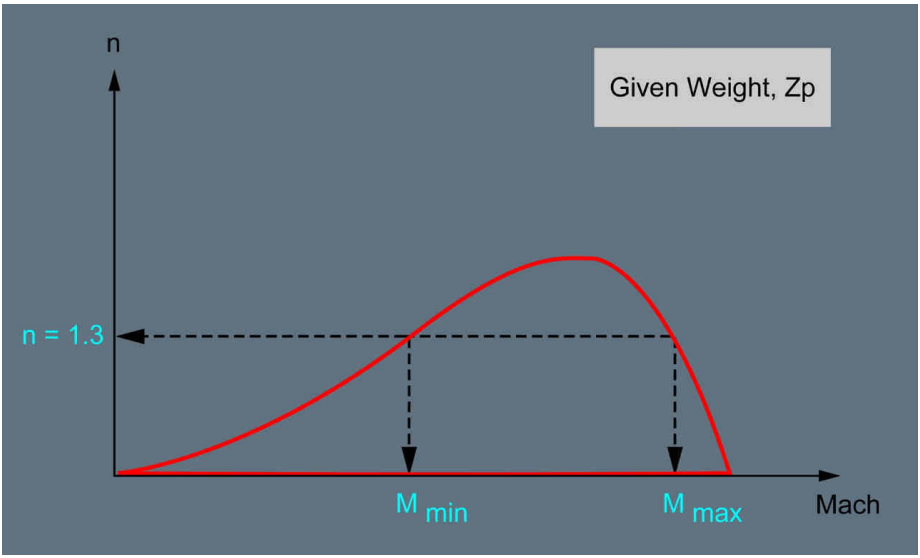
Applicable to: ALL

GENERAL

The buffet ceiling depends on the buffet margin value (generally fixed to 1.3).

L2 The variation of the load factor versus Mach is as follows:

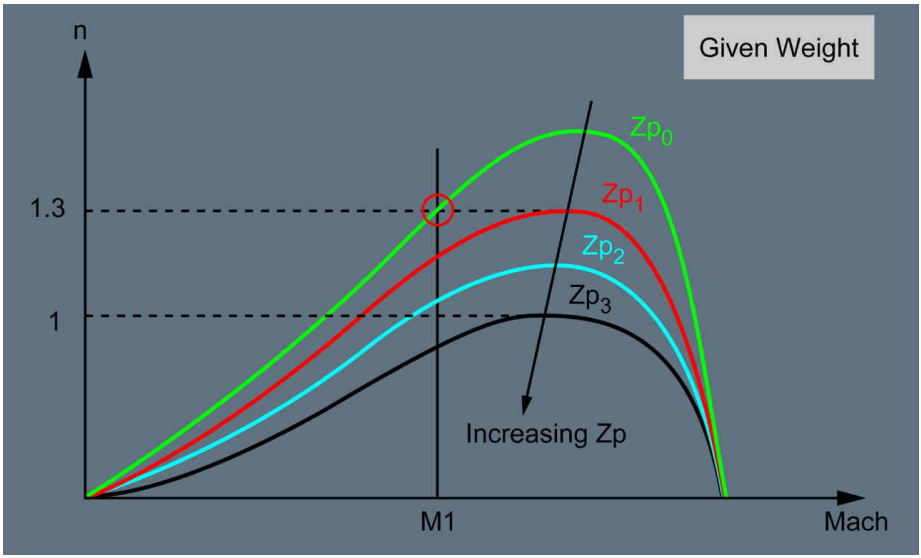
Load Factor versus Mach



For given weight and pressure altitude, if the Mach is included in the lift area (between M_{min} and M_{max}), the aircraft can bear a load factor up to 1.3 without buffeting (i.e. a 40 ° turn).

The variation of the lift area versus pressure altitude is as follows:

Lift Area versus Pressure Altitude



So, for a Mach M1 and a load factor of 1.3 g, the pressure altitude Zp_0 is the buffet ceiling. Indeed, M1 is one of both limits of the lift area at Zp_0.

L1 At given weight, the buffet ceiling is defined as the pressure altitude for which, at the desired load factor, the considered Mach is one of both limits of the lift area.

CRZ

The buffet ceiling is determined for Fixed Speed and Turbulence Speed cruise types.
For the ECON (CI) cruise type, the 1.3 g buffet ceiling is one of the criteria that REC MAX altitude must respect.

OPTIMUM ALTITUDE

Applicable to: ALL

OPTIMUM ALT

The optimum altitude definition depends on the cruise type.

ECON (CI)

The optimum altitude (OPT) displayed on the FMS-PERF page and the optimum altitude (OPTIMUM ALT) determined by the OIS IN-FLT PERF Cruise computation for a given Cost Index (CI) are the result of a minimum cost analysis. To determine these optimum altitudes, both the FMS and IN-FLT PERF calculate the value of the Cost Function (CF) based on the CI at 500 ft increment altitudes (these altitudes are called trial altitudes). The altitude that provides the lowest value for the CF is displayed as OPT on the FMS-PERF page and as OPTIMUM ALT on the OIS IN-FLT PERF.

These optimum altitude computations take into account a large number of parameters. The FMS and the OIS consider some of these parameters in a different manner. Therefore, OPT on the FMS and OPTIMUM ALT on the OIS may differ.

L2 The main contributor to any difference between OPT on the FMS and OPTIMUM ALT on the OIS is the wind.

L3 On the FMS, the flight crew can enter (or upload via ACARS) a vertical wind profile for each waypoint along the route. This vertical wind profile includes up to 5 altitudes. On the OIS IN-FLT PERF, the flight crew only enters the local wind at the current altitude for the computation.

L2 The relevance of the FMS altitude optimization mainly depends on the accuracy of the entered wind profile. The simplified wind model used in the OIS IN-FLT PERF computation may result in a less accurate altitude optimization than the FMS one.

To a lesser extent, the other contributors to any difference between OPT on the FMS and OPTIMUM ALT on the OIS are:

- The weight

L3 The FMS includes a prediction of gross weight reduction due to the fuel consumed during the climb to the trial altitude, while the OIS IN-FLT PERF makes a comparison at the entered weight

L2 - The performance model

L3 The FMS uses a simplified performance model (FMS performance database), due to the real time computation constraints, while the OIS IN-FLT PERF uses the best available first principle model of the aircraft (IFP model). The linearization and the smoothing of the data in the FMS model may lead to differences with the first principle model

L2 - The FMS top of descent

L3 The FMS avoids climbs shortly before the top of descent

L2 - The FMS smooth display update.

L3 The FMS updates the optimum altitude value if the CF of the new optimum altitude is better by at least 0.02 KG/NM than the CF of the previous optimum altitude.

L2 For the temperature assumption on the optimum altitude computation, the FMS extrapolates the current ΔISA to the trial altitude in the same way as the OIS. Therefore, if the flight crew enters the current ΔISA into the OIS IN-FLT PERF, the temperature assumptions for both the FMS and OIS are the same.

L1 **FIXED SPEED, LRC SPEED, GREEN DOT SPEED, TURBULENCE SPEED**

The optimum altitude is the altitude for which the Specific Range (SR) is maximum.
When the flight crew selects a Non Standard Configuration (NSC) item with an associated maximum altitude, the optimum altitude computed and displayed by IN-FLT PERF is limited by the maximum altitude of the NSC item.

MAXIMUM SPEED

The optimum altitude is the altitude for which the TAS is maximum.
When the flight crew selects a Non Standard Configuration (NSC) item with an associated maximum altitude, the optimum altitude computed and displayed by IN-FLT PERF is limited by the maximum altitude of the NSC item.

STEP CLIMB

Applicable to: ALL

GENERAL

An ideal cruise would follow the optimum altitude in a continuous climb. But ATC requires level flight cruise.
To maintain an optimum profile, step climbs between two flight levels are required as soon as the upper flight level is better than the current one.

CRZ

The weight displayed on the ALT subpanel is the one at which the next step climb should be initiated.
Even if the current pressure altitude does not respect the selected altitude rule, the step climb is calculated for the next higher flight level in accordance with the selected altitude rule.

L2 The criterion used to determine the weight (at which the next step climb should be initiated) depends on the cruise type:

- Cost function for ECON (CI)
- SR for Fixed Speed, LRC Speed, Green Dot Speed, Turbulence Speed.

SPECIFIC RANGE EQUIVALENCE

Applicable to: ALL

GENERAL

The wind speed may vary with altitude.
the cost function and the SR depend on the ground speed and thus on wind. The wind speed profile may thus shift the optimum altitude from the level of the optimum altitude in a theoretical calm atmosphere to a different level in an atmosphere with a wind variation.

CRZ

ECON (CI)

The SPECIFIC RANGE EQUIVALENCE table displays the minimum required wind difference at four flight levels (one above and three below the current cruise altitude) so as to the cost function at these flight levels is at least equal to the cost function at the current cruise altitude.
Any strong tail wind component would make one of these altitudes more advantageous than the current one.

FIXED SPEED, LRC SPEED, GREEN DOT SPEED, TURBULENCE SPEED

The SPECIFIC RANGE EQUIVALENCE table displays the minimum required wind difference at four flight levels (one above and three below the current cruise altitude) so as to the SR at these flight levels is at least equal to the SR at the current cruise altitude.
Any strong tail wind component would make one of these altitudes more advantageous than the current one.

Speed

MACH

Applicable to: ALL

GENERAL

The Mach number is defined as the ratio between TAS and the speed of sound.

CRZ

The SPEED subpanel displays the Mach number for current conditions.

ECON (CI)

The Mach displayed corresponds to the ECON Mach for current conditions.

LRC SPEED

The Mach displayed corresponds to the LRC Mach (or the Mach limited by the available thrust) for current conditions.

CALIBRATED AIR SPEED

Applicable to: ALL

GENERAL

The Calibrated Air Speed (CAS) is the speed resulting from the difference between the measured pressures (total and static).
A correction is made on the CAS to obtain the Indicated Air Speed (IAS). This correction takes into account the measurement errors on pressures, which affect CAS.

CRZ

The SPEED subpanel displays the CAS for current conditions.

Note: In normal CRZ conditions, there is a very little difference between CAS and IAS.

TRUE AIR SPEED

Applicable to: ALL

GENERAL

An aircraft in flight moves in an air mass, which is itself in motion compared to the earth. The True Air Speed (TAS) represents the aircraft speed in the airflow.

L2 TAS may be obtained from CAS, using the air density and a compressibility correction.

L1 **CRZ**

The SPEED subpanel displays the TAS for current conditions.
The flight crew may crosscheck the IN-FLT PERF TAS and GS with the ND ones.

N1

Applicable to: ALL

GENERAL

N1 is the rotation speed of the low pressure rotor. It is expressed as a percentage of the maximum rotation speed of the low pressure rotor. The FADEC uses the N1 parameter for engine control and monitoring. The N1 appears on the EWD .

L2 For more information about the N1, *Refer to DSC-70-15-10 Engine Description - LP* .

L1 **CRZ**

IN-FLT PERF displays the N1 to fly the aircraft in the current conditions of the cruise.

Detailed Results

TABLE RESULTS SUBPANEL

Applicable to: ALL

The TABLE RESULTS subpanel provides the detailed information for the cruise. The parameters displayed depend on the Operator customization.
The parameters are calculated for several cruise points by decreasing the current weight of the aircraft.

WGHT

This column displays the weights for which all the parameters are calculated.

FF

This column displays the instantaneous All Engine Fuel Flow (ALL ENG FF) for each intermediate weight.

L2 For more information about the ALL ENG FF, *Refer to PER-IFT-CRZ-CRR-CRF Fuel Flow* .

L1 CAS

This column displays the instantaneous Calibrated Air Speed (CAS) for each intermediate weight.

L2 For more information about the CAS , *Refer to PER-IFT-CRZ-CRR-CRS Calibrated Air Speed* .

L1 MACH

This column displays the instantaneous Mach number for each intermediate weight.

L2 For more information about the Mach number, *Refer to PER-IFT-CRZ-CRR-CRS Mach* .

L1 TAS

This column displays the instantaneous True Air Speed (TAS) for each intermediate weight.

L2 For more information about the TAS , *Refer to PER-IFT-CRZ-CRR-CRS True Air Speed* .

L1 THR

This column displays the instantaneous THR for each intermediate weight.

L2 For more information about the THR , *Refer to PER-IFT-CRZ-CRR-CRF THR* .

L1 SR

This column displays the instantaneous Specific Range (SR) for each intermediate weight.

L2 For more information about the SR , *Refer to PER-IFT-CRZ-CRR-CRF Specific Range* .

L1 AOA

This column displays the instantaneous Angle Of Attack (AOA) for each intermediate weight.

L2 AOA represents the angle between the aerodynamic chord and the aerodynamic axis defined by the speed direction.

L1 **N1**

This column displays the instantaneous N1 for each intermediate weight.

L2 For more information about the N1 , *Refer to PER-IFT-CRZ-CRR-CRS N1* .

GRAPH RESULTS SUBPANEL

Applicable to: ALL

The flight crew can plot cruise parameters versus weight using the GRAPH RESULTS subpanel. The possible parameters depend on the Operator customization of the TABLE RESULTS.

ADDITIONAL INFORMATION

When ALT is selected as the ordinate parameter, the following information is displayed on the graph:

- The cruise profile
- The optimum altitude
- The limit altitudes:
  - The maximum certified altitude
  - The maximum cruise altitude, except for ECON (CI)
  - The buffet ceiling, for Fixed Speed and Turbulence Speed
  - The REC MAX altitude for ECON (CI).
- The airspace levels of the selected altitude rule.

Intentionally left blank

IN-FLT PERF APPLICATION - DES MODULE

Applicable to: ALL

GENERAL

The descent phase starts at the Top of Descent (T/D) and ends at landing or level off.

DES

The IN-FLT PERF application is made of 6 modules (CLB, CRZ, DES, HLD, PLAN and ATMO).

The DES module provides the flight crew with a means to obtain descent performance data for:
- Given meteorological conditions
- A given aircraft configuration including non standard ones (engines out, landing gear down)
- Various speed schedules.

The main results of this module are:
- Fuel, time, and distance to landing or level off
- Level off.

Intentionally left blank

DES MODULE INTERFACE

Applicable to: ALL

IN-FLT PERF DES Module Interface

CONDITIONS

The flight crew can define the current outside conditions and the aircraft configuration.
For more information about the CONDITIONS panel, *Refer to PER-IFT-DES-CDT CONDITIONS Panel* .

DESCENT DATA

The flight crew can define the data of the descent phase.
For more information about the DESCENT DATA panel, *Refer to PER-IFT-DES-DSD DESCENT DATA Panel* .

AIRCRAFT STATUS

The flight crew can select CDL items and non standard configuration items.
For more information about the AIRCRAFT STATUS panel, *Refer to PER-IFT-ACS AIRCRAFT STATUS Panel* .

RESULTS

The RESULTS panel displays the essential information for the descent phase.

For more information about the RESULTS panel, Refer to Descent Results.

CONDITIONS PANEL

Applicable to: ALL

The CONDITIONS panel provides the following information:

- Wind
- Heading
- Temperature (Δ ISA)
- Anti-ice
- Gross weight
- CG
- Airflow.

CONDITIONS Panel

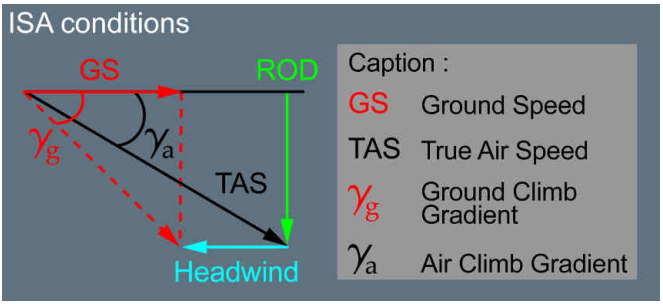
WIND

Applicable to: ALL

GENERAL

A constant wind component has no influence on the Rate of Descent (ROD), but impacts the descent angle.

Headwind Effect on Descent Flight Path



L2 A headwind component increases the flight path angle and decreases the ground distance from the Top of Descent (T/D).
The air climb gradient remains unchanged, whatever the wind component. So, the fuel and the time necessary to descent from the T/D to the final level stay the same.

L3 This is not applicable to a descent at Cost Index (CI), as the ECON descent Mach slightly depends on the wind.

L1 A longitudinal headwind component decreases the ground distance to reach the target pressure altitude.
Crosswind does not affect descent performance and is provided for information only.

DES

There are two ways to define wind values:
- Longitudinal Speed Component
- Direction/Speed Combination.

LONGITUDINAL SPEED COMPONENT

The flight crew enters the longitudinal component with:
- H or HD followed by the headwind speed (e.g. H10 or HD5), or
- T or TL followed by the tailwind speed (e.g. T6 or TL8).

Wind Values Input - Longitudinal Speed Component

DIRECTION/SPEED COMBINATION

The flight crew enters the wind direction and the wind speed.
The entry is projected along the heading and perpendicular to the heading.
The longitudinal projection follows the same display rules as the speed entry.

IN-FLT PERF displays the crosswind as:
- R, if the wind comes from the right, or
- L, if the wind comes from the left.

Wind Values Input - Direction/Speed Combination

HEADING

Applicable to: ALL

GENERAL

The heading defines the axis on which the wind is projected.

DES

The IN-FLT PERF heading and wind direction have to be both entered in either magnetic or true north.

The HDG field is only displayed if a wind has been entered in a combination of a direction and a speed.

L2 For more information about the wind, *Refer to Descent - Wind* .

TEMPERATURE

Applicable to: ALL

GENERAL

When temperature (SAT or ΔISA) increases, air density decreases, therefore:

- Descent gradient remains constant

L2 Assuming the "Idle" thrust rating, descent gradient mostly depends on the lift to drag ratio, which is independent from the temperature.

L1 - True Air Speed (TAS) increases

L2 At fixed Calibrated Air Speed (CAS), TAS is inversely proportional to air density, which decreases with temperature.
At fixed Mach, TAS increases with temperature.

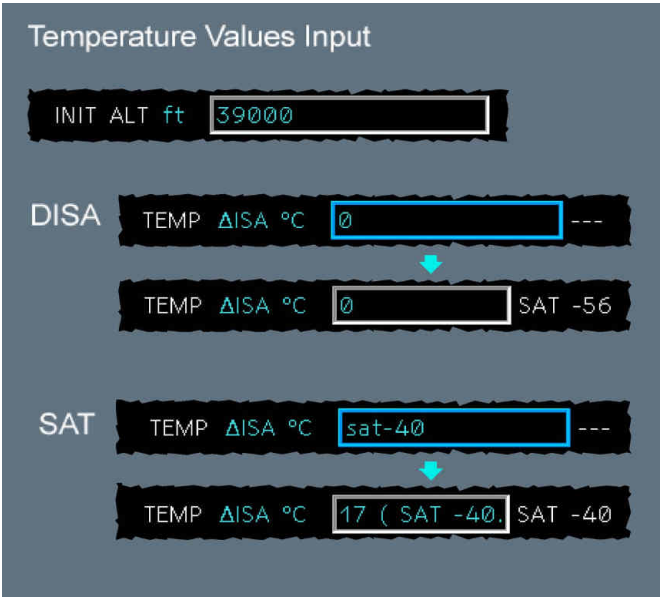
L1 - Rate of Descent (ROD) decreases

L3 ROD is a function of descent gradient (GRDT), TAS and ΔISA.
ROD can be expressed as ROD = TAS × sin (GRDT) × f(ΔISA).
The function f(ΔISA) is equal to 1 in ISA conditions, and decreases with ΔISA.
The increment in TAS is offset by the decrement due to f(ΔISA).

L1 - Fuel, time and distance to reach the target pressure altitude increase.

DES

Temperature Values Input



The TEMP field corresponds to a deviation from ISA law (ΔISA).

The flight crew member can enter a temperature as:
- A ΔISA, or
- A Static Air Temperature (SAT) at initial pressure altitude, which is automatically converted into a ΔISA.

ANTI-ICE

Applicable to: ALL

GENERAL

Anti-ice increases engine bleed. The FADEC offsets the increase in engine bleed by increasing the actual thrust calculated from internal engine parameters. The increment in net thrust is appreciable as the engine is more efficient compared without anti-ice.

Thus, in the case of ENG and/or WING anti-ice:

- Descent gradient decreases

L2 Descent gradient depends on excess thrust, which is negative in descent. With anti-ice, excess thrust increases but is still negative. Therefore it decreases in absolute value.

L3 In descent, excess thrust is the difference between net thrust and drag, which is negative as thrust rating is close to zero.

L1
- Rate of Descent (ROD) decreases
- Fuel, time and distance to reach the target pressure altitude increase.

IN-FLT PERF

IN-FLT PERF has four anti-ice options:

- Off
- Engine
- Total
- Severe Icing.

  The flight crew may use the Severe Icing option to assess the impact of ice accretion on fuel consumption and ceilings.

GROSS WEIGHT

Applicable to: ALL

GENERAL

An increase in weight leads to:

- A decrease in the descent gradient and Rate Of Descent (ROD)

L3 If TAS were constant with altitude at given CAS or Mach, descent gradient (GRDT) and ROD would be inversely proportional to the weight.

$$\sin\left(\text{GRDT}\right) = \frac{\left(\text{Thrust - Drag}\right)}{\text{Weight}} - \frac{1}{g} \times \frac{d}{dt}\left(\text{TAS}\right)$$

L1 - An increase in fuel, time and distance to reach the target pressure altitude.

DES

The flight crew enters the current aircraft weight at start of descent calculation.
This gross weight (GROSS WGHT field) must be between the Operating Empty Weight (OEW) and the Maximum Design Takeoff Weight (MTOW).

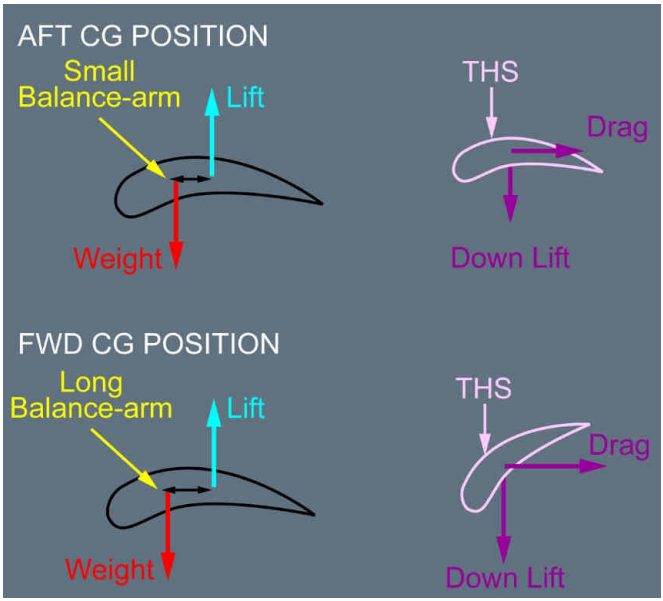
CG

Applicable to: ALL

GENERAL

The Center of Gravity (CG) position impacts the forces applied on the aircraft. As a result, it impacts aircraft performance.

CG Position



L2 In order to keep the aircraft level, the Trimmable Horizontal Stabilizer (THS) creates a downward force that counters the pitch down moment due to the distance between the center of lift and the center of gravity. The larger this lever arm, the higher the down lift that must be generated by the THS, and the higher the drag.

L1 IN-FLT PERF

The CG field is expressed in % of the Mean Aerodynamic Chord (MAC).

AIRFLOW

Applicable to: ALL

GENERAL

High airflow increases engine bleed. The FADEC offsets the increase in engine bleed by increasing the actual thrust calculated from internal engine parameters. But, the increment in net thrust is not really appreciable as the engine is not more really efficient than without airflow.

Thus, in the case of an increase in airflow:

- Descent gradient slightly decreases

L2 Descent gradient depends on excess thrust, which is negative in descent. With airflow, excess thrust slightly increases but is still negative. Therefore it slightly decreases in absolute value.

L3 In descent, excess thrust is the difference between net thrust and drag, which is negative as thrust rating is close to zero.

L1
- Rate of Descent (ROD) slightly decreases
- Fuel increases
- But time and distance to reach the target pressure altitude are not very impacted

L3 The slight decrement in descent gradient and ROD tends to increase time and distance. On the contrary, the overconsumption tends to decrease time and distance by decreasing the aircraft's weight.

L1 IN-FLT PERF

IN-FLT PERF has five airflow options:

- OFF
- LO
- MAN
- NORM
- HI.

IMPACT OF FWD CARGO COOLING

When FWD cargo cooling is active, the airflow automatically increases, and so the engine bleed. The IN-FLT PERF airflow settings reflect the engine bleed with FWD cargo cooling OFF.
The flight crew applies the following equivalences to obtain an engine bleed that considers the effect of FWD cargo cooling:

ENG OPERATIVE	AIR FLOW Selector	FWD Cargo Cooling	Select IN-FLT PERF setting
4	LO	ON	MAN
	MAN		HI

Intentionally left blank

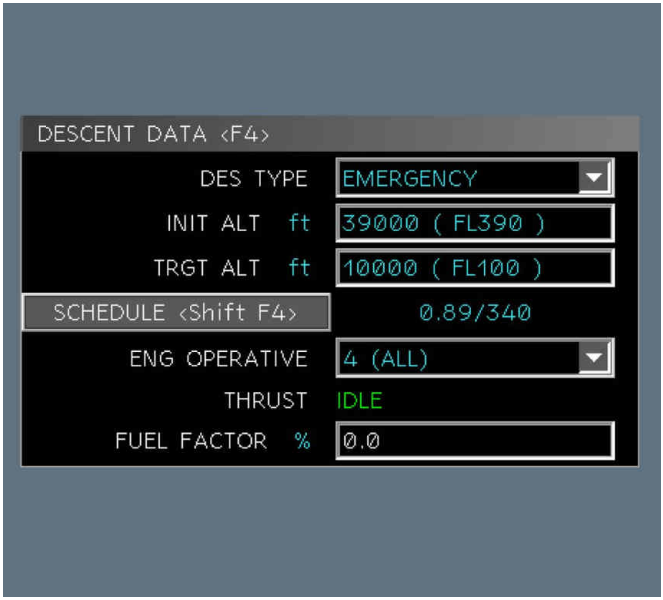
DESCENT DATA PANEL

Applicable to: ALL

The DESCENT DATA panel provides the following information:

- Descent type preset
- Initial altitude
- Target altitude (except for the OBSTACLE descent type preset)
- Descent schedule (speed type, speed brakes, specific information on the descent speed schedule)
- Engines operative
- Thrust lever position
- Fuel factor.

DESCENT DATA Panel



DESCENT TYPE PRESET

Applicable to: ALL

The flight crew uses the DES TYPE PRESET drop-down list to define the descent type.

The following descent types are available:

- ECON (CI)
- STANDARD
- GIVEN V/S
- EMERGENCY

In OEI , two additional descent types are available:

- OBSTACLE

L2 For more information about the OBSTACLE descent type, *Refer to PER-IFT-OEI-OBS-ABV Drift Down - Green Dot* .

L1 - EO-STD

L2 For more information about the EO-STD descent type, *Refer to PER-IFT-OEI-STD-ABV Descent to EO MAX Altitude* .

INITIAL ALTITUDE

Applicable to: ALL

The initial altitude is the pressure altitude at which the computation of a descent begins.

TARGET ALTITUDE

Applicable to: ALL

The target altitude is the pressure altitude at which the computation should stop.
The TRGT ALT field is not displayed for the OBSTACLE descent type.

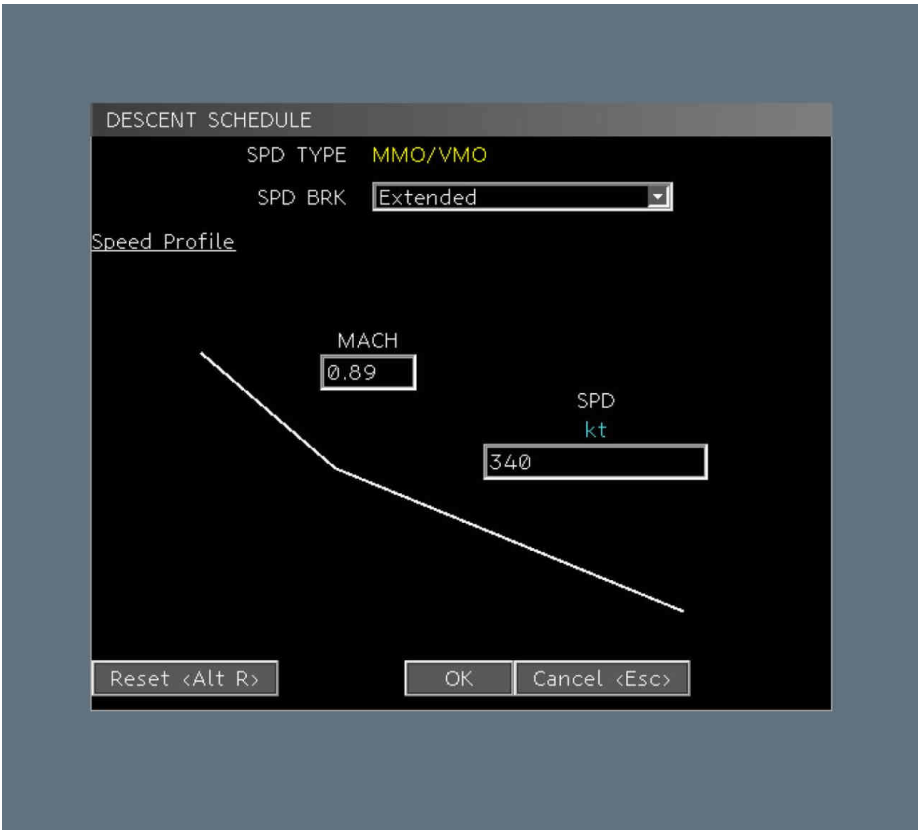
DESCENT SCHEDULE

Applicable to: ALL

The DESCENT SCHEDULE subpanel provides the following information:

- The speed type
- The speed brakes
- The speed profile.

DESCENT SCHEDULE Subpanel



SPEED TYPE

The flight crew uses the SPD TYPE drop-down list to define the speed profile type according to the selected descent type.

If the flight crew has selected ECON (CI) as descent type, the speed type is automatically Open (CI) .

L2 For more information about the ECON(CI) Open (CI) descent type, *Refer to PER-IFT-DES-ECI General* .

L1 If the flight crew has selected STANDARD as descent type, the following speed types are available:

- Fixed Speed

L2 For more information about the STANDARD Fixed Speed descent type, *Refer to PER-IFT-DES-STD-FSP General* .

L1 - Turbulence Speed

L2 For more information about the STANDARD Turbulence Speed descent type, *Refer to PER-IFT-DES-STD-TSP General* .

L1 If the flight crew has selected GIVEN V/S as descent type, the speed type is automatically Fixed Speed .

L2 For more information about the GIVEN V/S Fixed Speed descent type, *Refer to PER-IFT-DES-GVS General* .

L1 If the flight crew has selected EMERGENCY as descent type, the speed type is automatically MMO/VMO .

L2 For more information about the EMERGENCY MMO/VMO descent type, *Refer to PER-IFT-DES-EMG General* .

L1 If the flight crew has selected OBSTACLE as descent type, the following speed types are available:

- Green Dot

L2 For more information about the OBSTACLE Green Dot descent type, *Refer to PER-IFT-OEI-OBS-ABV Drift Down - Green Dot* .

L1 - Fixed Speed

L2 For more information about the OBSTACLE Fixed Speed descent type, *Refer to PER-IFT-OEI-OBS-ABV Drift Down - Fixed Speed* .

L1 If the flight crew has selected EO-STD as descent type, the speed type is automatically Mach/CAS - V/S .

L2 For more information about the EO-STD Mach/CAS - V/S descent type, *Refer to PER-IFT-OEI-STD-ABV Descent to EO MAX Altitude* .

SPEED BRAKES

GENERAL

The speed brakes may be used in order to increase the Rate of Descent (ROD).
They are especially used in the case of an emergency descent.

DES

The flight crew uses the SPD BRK drop-down list to select the position of the speed brakes, which are:
- Retracted, or
- Extended.

By default, the speed brakes are “Retracted” except for the IN-FLT PERF EMERGENCY descent type.

ENGINES OPERATIVE

Applicable to: ALL

GENERAL

The number of engines operative does not really impact the descent performance.
But, the number of engines operative directly impacts the type of descent (e.g. drift down after an engine failure in OBSTACLE strategy).

DES

The flight crew selects the number of engines operative:
- 4 (ALL), or
  Except for the OBSTACLE and EO-STD descent types.
- 3, or
- 2, or
  Except for the GIVEN V/S descent type.
- 1, or
  Except for the GIVEN V/S and ECON (CI) descent types.
- 0.
  Only for the OBSTACLE descent type.

Note: The All Engines Flame Out Descent computation fails.

THRUST

Applicable to: ALL

GENERAL

The standard descent thrust rating is “Idle”. This thrust rating is delivered when the thrust lever is in the IDLE detent. However, if the thrust lever is in the CL detent with A/THR engaged, the minimum thrust rating is also "Idle".
However, in the case of an engine failure, the throttle lever is set in the MCT detent. The “Maximum Continuous Thrust” rating is used.

L2 For more information, refer to Thrust Ratings.

L1 DES

The thrust rating depends on the descent type and the number of engines operative.

OBSTACLE

- MCT, whatever the number of engines operative (less than all engines).

ECON (CI)

- CL (A/THR), if AEO
- MCT, if OEI or TEI.

STANDARD

- CL (A/THR), if AEO
- IDLE, whatever the number of engines operative
- MCT, if at least one engine is inoperative.

GIVEN V/S

- CL (A/THR), if AEO
- MCT, if OEI.

EMERGENCY

- IDLE, whatever the number of engines operative.

EO-STD

- MCT, whatever the number of engines operative (less than all engines).

FUEL FACTOR

Applicable to: ALL

GENERAL

The performance factor for FMS predictions (FMS PERF FACTOR) is the sum of the Basic FMS PERF FACTOR and the Monitored Fuel Factor.

BASIC FMS PERF FACTOR

The Basic FMS PERF FACTOR correction is applied when the aircraft FMS database does not exactly fit to the aircraft model. It is published for each FMS Performance Data Base (PDB).
It results in FMS predictions consistent with the level reflected by the uncorrected IN-FLT PERF application, also called the book level.

MONITORED FUEL FACTOR

The actual airframe drag and engine performance deviate from the nominal model due to the aircraft's aging process.
The Monitored Fuel Factor is used to correct the performance book level to the actual performance level in order to permit realistic fuel predictions.
The Monitored Fuel Factor is defined as a percentage increase or decrease of the nominal Specific Range (SR) value.

IN-FLT PERF

The IN-FLT PERF fuel factor corresponds to the sum of:
- The Monitored Fuel Factor, and
- A positive performance prediction adjustment (if enabled, and at flight crew discretion).

L2 This allows the flight crew to adjust performance predictions to a drag increase due to non-quantified aerodynamic sources.

L1 When no such performance adjustment is required, the IN-FLT PERF fuel factor may thus differ from the FMS one by the Basic FMS PERF FACTOR.

Intentionally left blank

GENERAL

Applicable to: ALL

The ECON (CI) Open (CI) descent type enables the flight crew to emulate several MFD DES page performance predictions:

- ECON Mach and speed
- Distance to targeted altitude
- Time to targeted altitude.

Moreover, the ECON (CI) Open (CI) descent type provides some additional performance information.

L2 This is flown in managed speed/Mach target.

L3 The ECON (CI) Open (CI) descent type combines the use of the FMS managed speed/Mach targets with the physical model of the aircraft, whereas the FMS predictions use a simplified model of the aircraft.

COST INDEX

Applicable to: ALL

The Cost Index (CI) is defined as the ratio between Cost of Time per time unit (CT) and Cost of Fuel per mass unit (CF).
The CI value is expressed in hundreds of pounds per hour (100 lb/h).
The purpose of the CI concept is to reduce Direct Operating Costs (DOC).

L2 DOCs are made up of:

- Fixed costs
- Time-related costs, which can be expressed as CT × (trip time)
- Cost of fuel, which can be expressed as CF × (trip fuel).

SPEED PROFILE

Applicable to: ALL

GENERAL

A descent in managed speed/Mach target is generally operated using a speed profile divided into two main phases:

- An economic descent schedule (ECON Mach/ ECON IAS law)

L2 For more information about the economic descent schedule, *Refer to PER-IFT-DES-ECI Economic Descent Schedule* .

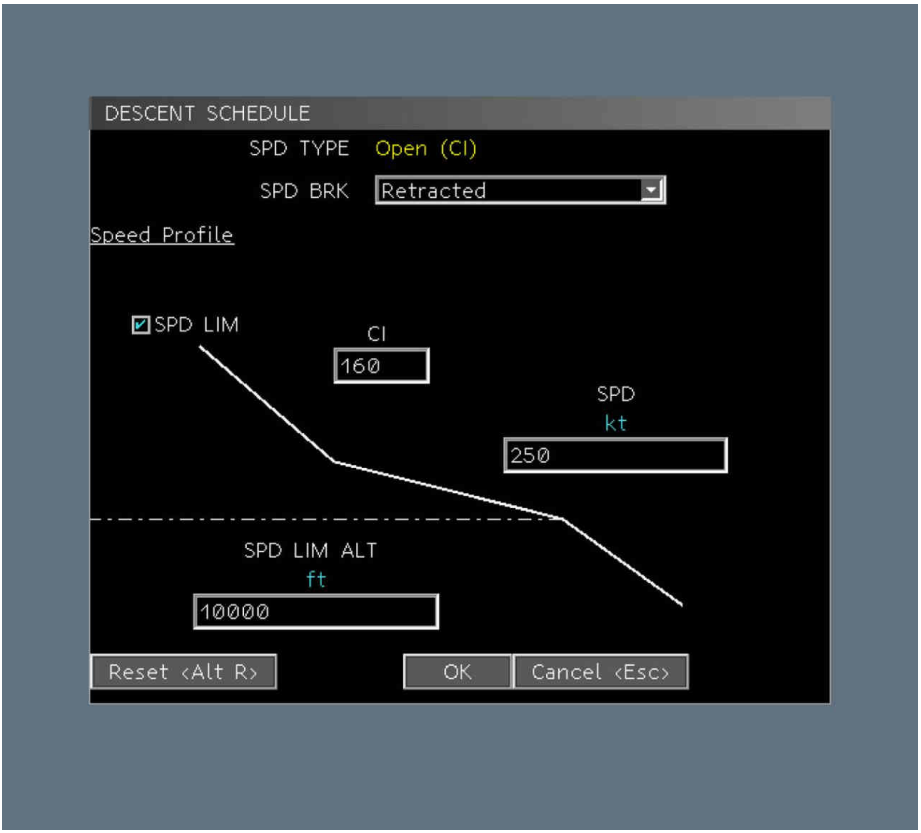
L1 - An possible descent speed limit phase.

L2 The descent speed limit is a speed constraint to be respected, at and below a specified altitude.

L1 DES

WITH A SPEED LIMIT

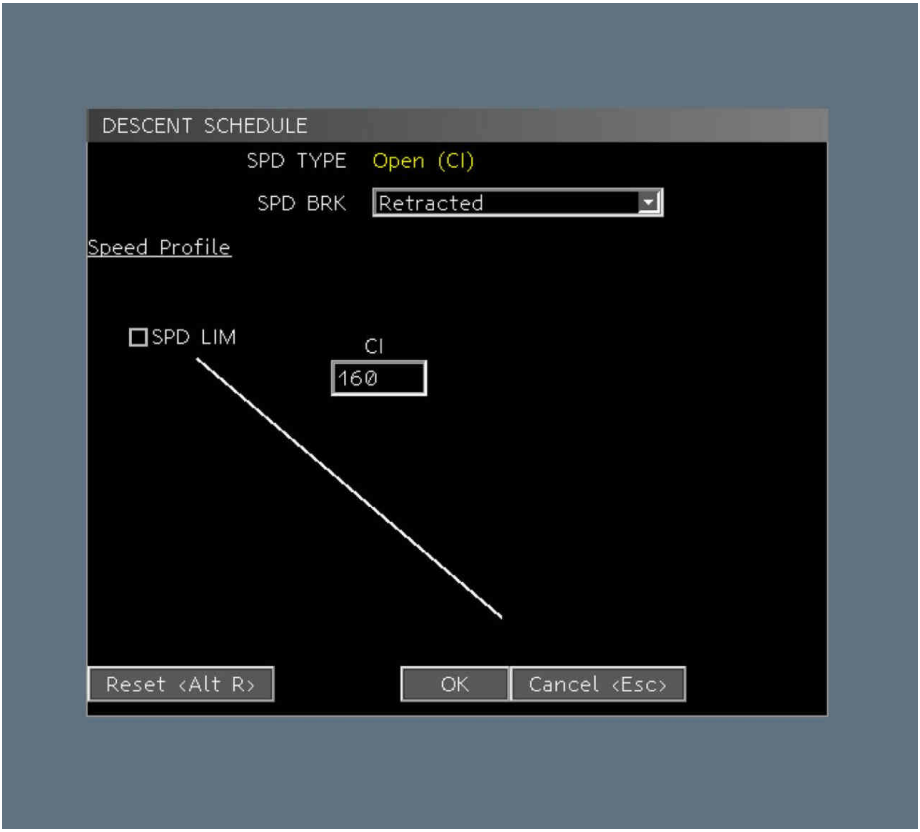
Speed Profile Subpanel - With a Speed Limit



The flight crew enters:
- The CI value used to manage the flight
- A descent speed limit CAS (SPD LIM)
- A descent speed limit altitude (SPD LIM ALT).

WITHOUT A SPEED LIMIT

Speed Profile Subpanel - Without a Speed Limit



The flight crew enters the CI value used to manage the flight.

ECONOMIC DESCENT SCHEDULE

Applicable to: ALL

An economic descent schedule is a predetermined Mach/ IAS descent speed law depending on CI .

L2 The Mach phase is flown at ECON Mach function of:

- CI
- Top of Descent (T/D) altitude
- Predicted weight at T/D altitude
- Temperature
- Wind.

For more information about the ECON Mach, *Refer to Cruise - ECON Mach* .

The IAS phase is flown at ECON IAS function of:

- CI
- T/D altitude
- Predicted weight at T/D .

Intentionally left blank

FIXED SPEED

Applicable to: ALL

The flight crew may use the STANDARD Fixed Speed descent type to calculate descent performance for a descent in selected speed/Mach target with a given fixed speed schedule. Usually, the speed schedule is the standard descent speed profile.

SPEED PROFILE

GENERAL

A descent in selected speed/Mach target is generally operated using a speed profile divided into three phases (MACH/SPD/SPD LIM).
The standard descent speed profile is M 0.85 /300 kt /250 kt with a speed constraint from FL 100.

Above the Crossover Altitude

This descent phase is operated at constant Mach (MACH).

L2 At constant Mach, TAS increases in descent.

L1 Below the Crossover Altitude

This descent phase is operated at constant IAS (SPD), which is maintained until the descent speed limit altitude.

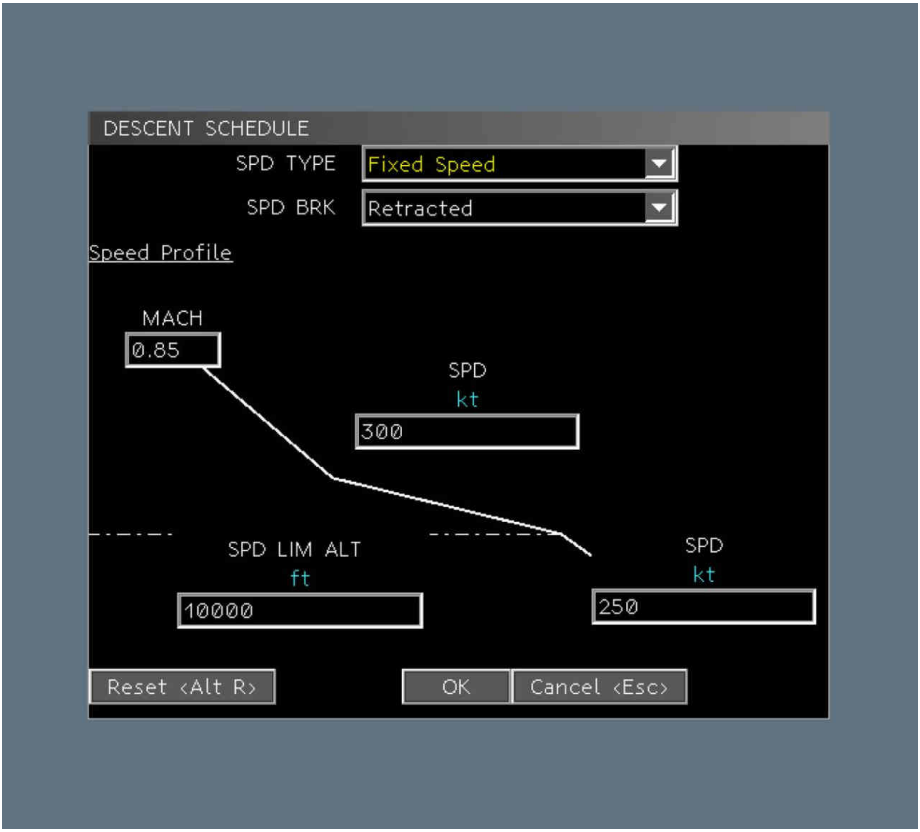
L2 The crossover altitude is the pressure altitude at which SPD and MACH are equal to the same TAS.
At constant IAS, TAS decreases in descent.

L1 Below the Descent Speed Limit Altitude

This descent phase is operated at constant IAS (SPD LIM).
The speed is limited by ATC and according to airspace rules.

DES

Speed Profile Subpanel



The flight crew enters:
- The descent speed Mach (MACH)
- The descent speed CAS (SPD)
- The descent speed limit altitude (SPD LIM ALT)
- The descent speed limit CAS (SPD LIM).

TURBULENCE SPEED

Applicable to: ALL

GENERAL

The flight crew may use the STANDARD Turbulence descent type to calculate descent performance for a descent in selected speed/Mach target operated through turbulence areas.

L2 Turbulence speeds are recommended when the aircraft flies in a turbulent atmosphere. They increase the margin to buffet onset, which is more likely to occur due to Angle Of Attack (AOA) variations induced by disturbances in these meteorological conditions.

L1 This is flown in selected speed/Mach target by manually setting the MAX TURB fixed IAS/Mach law on the AFS CP, computed by the FMC and indicated on the MFD PERF DES page (MAX TURB function).

This may also be flown in selected speed/Mach target by manually setting the turbulence descent speed profile on the AFS CP, given by the IN-FLT PERF Turbulence descent type.

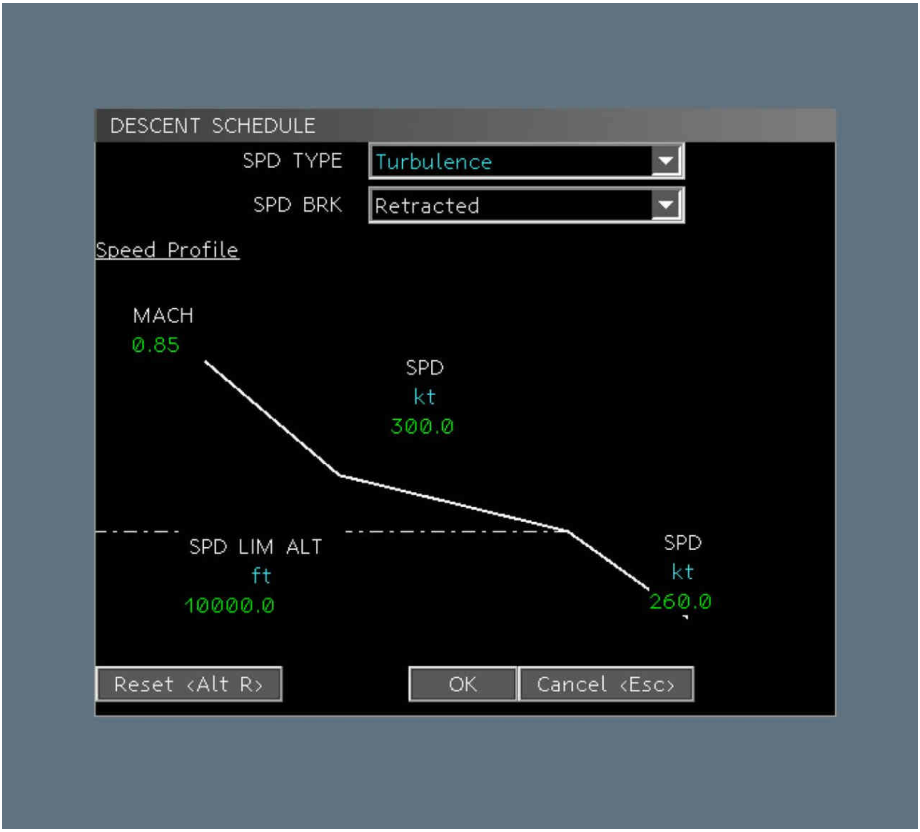
SPEED PROFILE

GENERAL

The recommended turbulence penetration airspeed (VRA/MRA) is between green dot and 300 kt/M 0.85.
The MAX TURB function indicated on the MFD PERF DES page displays the maximal speed/Mach not to exceed according to this recommendation.
The IN-FLT PERF Turbulence descent type philosophy is different. It enables to make a computation from the Operator's turbulence descent speed profile.
The optimum turbulence descent speed profile in terms of margin towards buffet onset is M 0.85/300 kt/260 kt with a speed constraint up to FL 100.

DES

Speed Profile Subpanel



GENERAL

Applicable to: ALL

The flight crew may use the GIVEN V/S Fixed Speed descent type to calculate descent performance for a descent in selected speed/Mach target at fixed Rate of Descent (ROD) with a given fixed speed schedule.

This is flown by engaging the basic vertical mode V/S on the AFS CP.

SPEED PROFILE

Applicable to: ALL

GENERAL

A descent in selected speed/Mach target is generally operated using a speed profile divided into three phases (MACH/SPD/SPD LIM).
The standard descent speed profile is M 0.85 /300 kt /250 kt with a speed constraint from FL 100.

ABOVE THE CROSSOVER ALTITUDE

This descent phase is operated at constant Mach (MACH).

L2 At constant Mach, TAS increases in descent.

L1 BELOW THE CROSSOVER ALTITUDE

This descent phase is operated at constant IAS (SPD), which is maintained until the descent speed limit altitude.

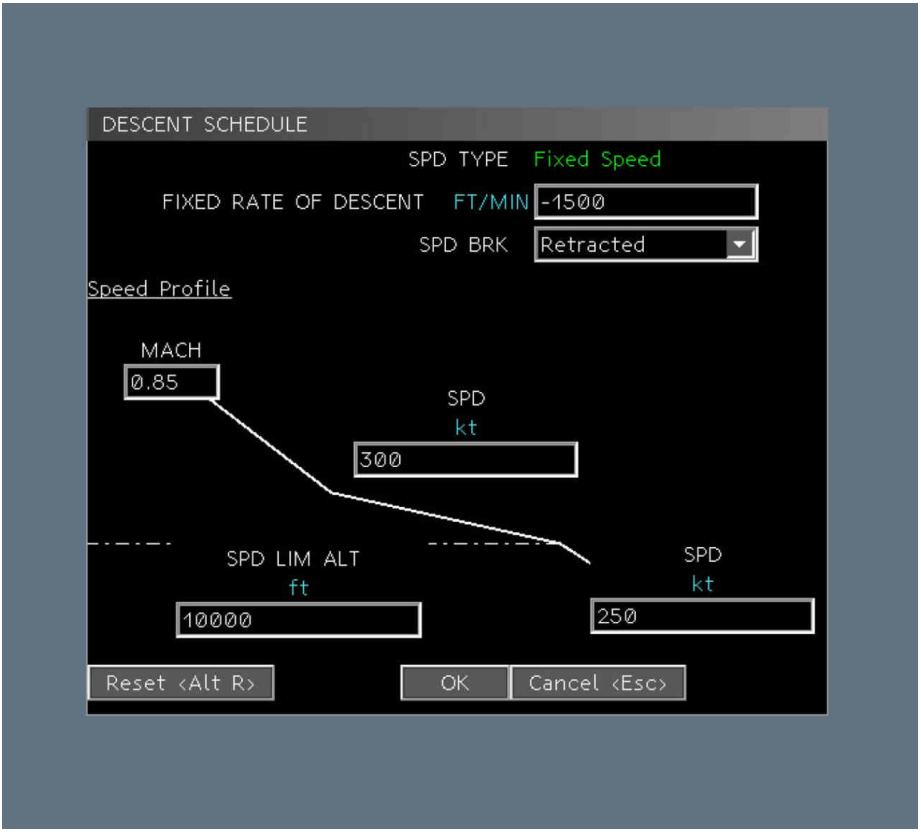
L2 The crossover altitude is the pressure altitude at which SPD and MACH are equal to the same TAS.
At constant IAS, TAS decreases in descent.

L1 BELOW THE DESCENT SPEED LIMIT ALTITUDE

This descent phase is operated at constant IAS (SPD LIM).
The speed is limited by ATC and according to airspace rules.

DES

Speed Profile Subpanel



The flight crew enters:

- The descent speed Mach (MACH)
- The descent speed CAS (SPD)
- The descent speed limit altitude (SPD LIM ALT)
- The descent speed limit CAS (SPD LIM).

Intentionally left blank

GENERAL

Applicable to: ALL

The flight crew may use the EMERGENCY MMO/VMO descent type to calculate descent performance for an emergency descent (e.g. due to a cabin pressurization failure).

SPEED PROFILE

Applicable to: ALL

The purpose of an emergency descent is to reach a specific FL as quickly as possible, i.e. with the highest Rate of Descent (ROD).

MMO/VMO is the best speed profile as it gives high RODs, which can be increased by extending the speed brakes, if needed.

L2 In fact, ROD increases with TAS.

Intentionally left blank

BASIC RESULTS PANEL

Applicable to: ALL

The basic RESULTS panel provides the essential information for the descent.

Basic RESULTS Panel

LEVEL OFF

Level off on the RESULTS panel is the pressure altitude at which the calculated Rate of Descent (ROD) is 0.

The level off is only available for the OBSTACLE Green Dot or Fixed Speed descent types.

TIME

Time on the RESULTS panel is the time elapsed from the initial pressure altitude to the target pressure altitude (or the level off for the OBSTACLE Green Dot or Fixed Speed descent types).

DISTANCE

Distance on the RESULTS panel is the distance covered from the initial pressure altitude to the target pressure altitude (or the level off for the OBSTACLE Green Dot or Fixed Speed descent types).

FUEL

FUEL on the RESULTS panel is the estimated fuel used from the initial pressure altitude to the target pressure altitude (or the level off for the OBSTACLE Green Dot or Fixed Speed descent types).

EO LRC CEILING

EO LRC Ceiling on the RESULTS panel is the highest pressure altitude that can be flown in level flight with long range cruise speed and at least one engine inoperative.
The EO LRC Ceiling is only available for the OBSTACLE Green Dot or Fixed Speed descent types and the EO-STD Fixed Speed descent type.

TABLE RESULTS SUBPANEL

Applicable to: ALL

The TABLE RESULTS subpanel provides the detailed information for the descent. The parameters displayed depend on the Operator customization.

ALT

This column displays the altitude from the initial pressure altitude to the target pressure altitude (or the level off pressure altitude) with a step of 5 000 ft.

ALTG

This column displays the geometric altitude corresponding to each intermediate pressure altitude.

TIME

This column displays the time elapsed from the initial pressure altitude to each intermediate pressure altitude.

FUEL

This column displays the fuel burnt from the initial pressure altitude to each intermediate pressure altitude.

DIST

This column displays the distance covered from the initial pressure altitude to each intermediate pressure altitude.

TAS

This column displays the instantaneous True Air Speed (TAS) at each intermediate pressure altitude.

MACH

This column displays the instantaneous Mach number at each intermediate pressure altitude.

CAS

This column displays the instantaneous Calibrated Air Speed (CAS) at each intermediate pressure altitude.

THR

This column displays the instantaneous THR at each intermediate pressure altitude.

L2 The THR value indicates the thrust used. It is shown as a % of the available thrust.

Assuming that the thrust achieved in windmilling is close to zero, the available thrust is the ratio of the actual thrust calculated from engine parameters to:

- The thrust achieved with TO thrust rating and bleeds OFF for Takeoff and Taxi
- The thrust achieved with GA thrust rating and bleeds OFF for all other flight phases (Climb, Cruise, Descent, Holding).

L1 **GRDT**

This column displays the instantaneous descent gradient at each intermediate pressure altitude.

L2 The descent gradient represents the angle between the horizontal axis and the aerodynamic axis defined by the speed direction.

L1 **AOA**

This column displays the instantaneous Angle Of Attack (AOA) at each intermediate pressure altitude.

L2 The angle of attack represents the angle between the aircraft axis and the aerodynamic axis defined by the speed direction.

L1 **RATE**

This column displays the instantaneous Rate Of Descent (ROD) at each intermediate pressure altitude.

L2 In ISA conditions, ROD represents the vertical component of the speed.
In ISA conditions, ROD = TAS × sin (GRDT) ~ TAS × GRDT.

L1 **PITCH**

This column displays the instantaneous pitch angle at each intermediate pressure altitude.

L2 The pitch angle represents the angle between the aircraft axis and the horizontal axis.

GRAPH RESULTS SUBPANEL

Applicable to: ALL

The flight crew can plot descent parameters versus each other using the GRAPH RESULTS subpanel.
The possible parameters depend on the Operator customization of the TABLE RESULTS.
Specific values can be read from the graph using the cross-hairs.

ADDITIONAL INFORMATION

When altitude is selected as the ordinate, the following additional elements are shown in the graph:

- If ECON (CI) or STANDARD is selected, a horizontal line is shown for the altitude value of the “End of repressurization segment”
- If OBSTACLE is selected, a horizontal line is shown for the altitude value of the “Transition Mach/CAS”
- If OBSTACLE or EO-STD is selected, a horizontal line is shown for the altitude value of the "EO LRC Ceiling".

Intentionally left blank

IN-FLT PERF APPLICATION - HLD MODULE

Applicable to: ALL

GENERAL

The holding phase, when required, starts before the landing phase above the destination or alternate airport.

Holding Fuel is one of the minimum recommended fuel quantities for a standard flight planning.

L2 For more information about the minimum recommended fuel quantities, *Refer to PER-IFT-FPL-MRF-RSF Holding Fuel* .

L1 HLD

The IN-FLT PERF application is made of 6 modules (CLB, CRZ, DES, HLD, PLAN and ATMO).

The HLD module provides the flight crew with a means to obtain holding performance data for:
- Given meteorological conditions
- A given aircraft configuration including non standard ones (engines out, landing gear down)
- Various holding strategies.

Two computation types are available:
- FUEL, to assess holding fuel for a given holding time
- TIME, to assess maximum holding time capability for a given fuel quantity (maximum endurance).

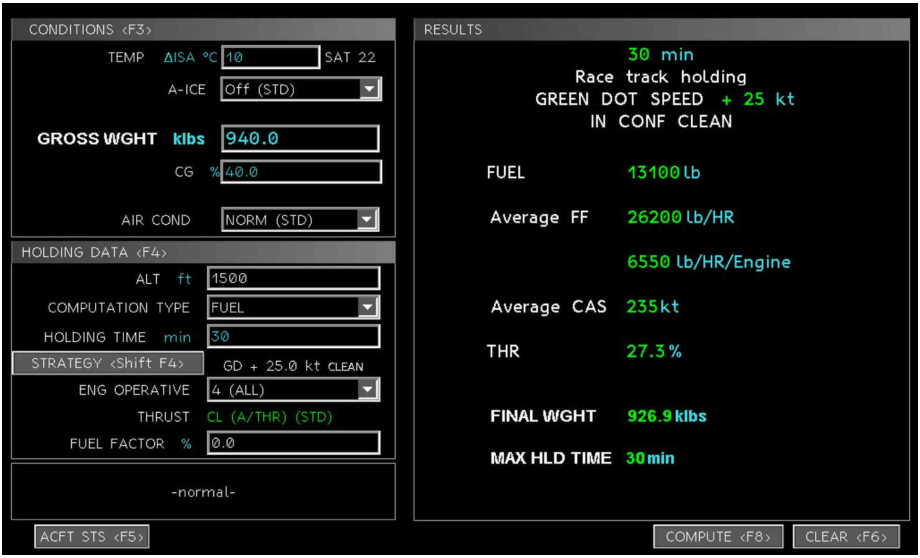
The main results of this module are:
- Holding fuel, holding time
- Average Fuel Flow (FF)
- Average CAS .

Intentionally left blank

HLD MODULE INTERFACE

Applicable to: ALL

IN-FLT PERF HLD Module Interface



CONDITIONS

The flight crew can define the current outside conditions and the aircraft configuration.
For more information about the CONDITIONS panel, *Refer to PER-IFT-HLD-CDT CONDITIONS Panel* .

HOLDING DATA

The flight crew can define the data of the holding phase.
For more information about the HOLDING DATA panel, *Refer to PER-IFT-HLD-HLD HOLDING DATA Panel* .

AIRCRAFT STATUS

The flight crew can select CDL items and non standard configuration items.
For more information about the AIRCRAFT STATUS panel, *Refer to PER-IFT-ACS AIRCRAFT STATUS Panel* .

RESULTS

The RESULTS panel displays the essential information for the holding phase.

For more information about the RESULTS panel, refer to Holding Results.

CONDITIONS PANEL

Applicable to: ALL

The CONDITIONS panel provides the following information:

- Wind
- Heading
- Temperature (Δ ISA)
- Anti-Ice
- Gross Weight
- CG
- Airflow.

CONDITIONS Panel

WIND

Applicable to: ALL

GENERAL

The influence of wind is only taken into account for a straight line holding pattern.
The wind affects the ground distance.
A tailwind will induce an increase in the ground distance.

HLD

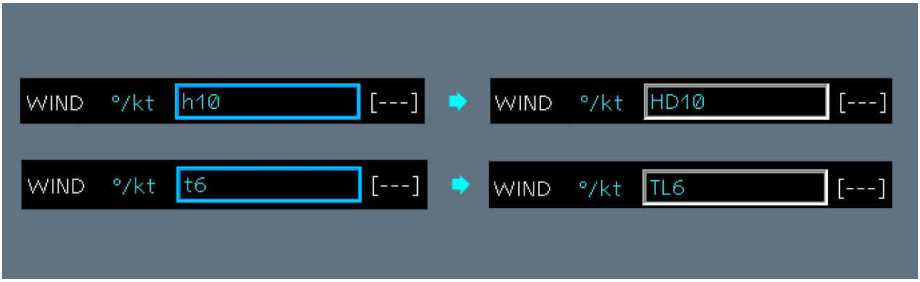
There are two ways to defining wind values:
- Longitudinal Speed Component
- Direction/Speed Combination.

The WIND field is only displayed in the case of a straight line holding pattern.

LONGITUDINAL SPEED COMPONENT

The flight crew enters the longitudinal component with:
- H or HD followed by the headwind speed (e.g. H10 or HD5), or
- T or TL followed by the tailwind speed (e.g. T6 or TL8).

Wind Values Input - Longitudinal Speed Component



DIRECTION/SPEED COMBINATION

The flight crew enters the wind direction and the wind speed.
The entry is projected along the heading and perpendicular to the heading.
The longitudinal projection follows the same display rules as the speed entry.

IN-FLT PERF displays the crosswind as:
- R, if the wind comes from the right, or
- L, if the wind comes from the left.

Wind Values Input - Direction/Speed Combination

HEADING

Applicable to: ALL

GENERAL

The heading defines the axis on which the wind is projected.

HLD

The IN-FLT PERF heading and wind direction have to be both entered in either magnetic or true north.

The HDG field is only displayed:
- If a wind has been entered in a combination of a direction and a speed
- In the case of a straight line holding pattern.

L2 For more information about the wind, *Refer to Holding - Wind* .

TEMPERATURE

Applicable to: ALL

GENERAL

An increase in temperature (SAT or ΔISA) leads to:

- A higher true altitude at fixed indicated altitude
- A higher True Air Speed (TAS) for the same Calibrated Air Speed (CAS)

L2 At fixed CAS, TAS is inversely proportional to air density, which decreases with temperature.

L1 - A higher required net thrust to fly this TAS.

L2 The net thrust is the difference between the gross thrust and the capturing drag. It is the thrust necessary to maintain the level flight.

L1 FUEL

When temperature increases:

- Fuel Flow (FF) increases
- THR increases

L2 The maximum available thrust decreases with temperature, and the required net thrust increases.

L1 - Distance increases

L2 TAS increases for the same CAS.

L1 - Fuel burnt increases for a given holding time.

TIME

When temperature increases:

- FF increases
- THR increases

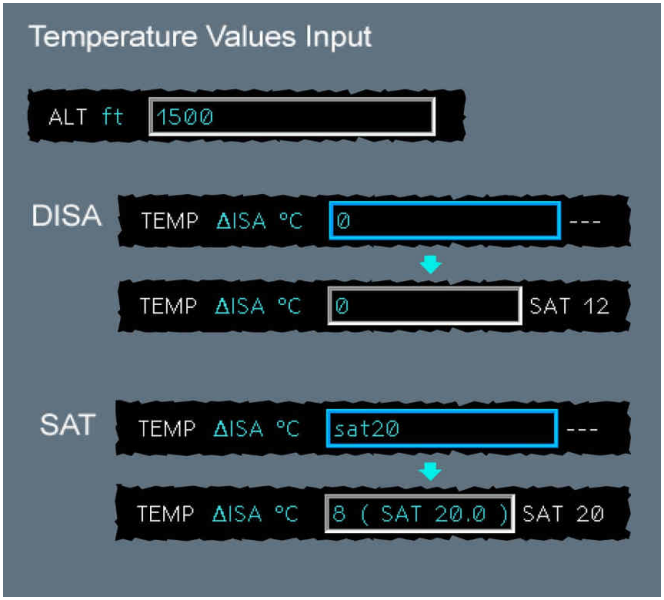
L2 The maximum available thrust decreases with temperature, and the required net thrust increases.

L1 - Maximum holding time decreases for a given fuel quantity
- Distance decreases.

L2 The increment in TAS does not off set the decrease in time.

L1 **HLD**

Temperature Values Input



The TEMP field corresponds to a deviation form ISA law (ΔISA).

The flight crew can enter a temperature as:
- A ΔISA, or
- A Static Air Temperature (SAT) at holding altitude, which is automatically converted into a ΔISA.

ANTI-ICE

Applicable to: ALL

GENERAL

Anti-ice increases engine bleed.

L2 The net thrust (which is the thrust necessary to maintain the level flight) stays the same. But, the increased bleed flow leads to an increased Fuel Flow (FF) to generate this thrust.

L1 **FOR A GIVEN HOLDING TIME**

In the case of ENG and/or WING anti-ice:
- FF increases
- THR increases
- Fuel quantity increases for a given holding time.

FOR A GIVEN HOLDING FUEL

In the case of ENG and/or WING anti-ice:
- FF increases
- THR increases
- Maximum holding time decreases for a given fuel quantity
- Distance decreases.

L2 The time decreases and TAS stays the same.

L1 **IN-FLT PERF**

IN-FLT PERF has four anti-ice options:
- Off
- Engine
- Total
- Severe Icing.

The flight crew may use the Severe Icing option to assess the impact of ice accretion on fuel consumption and ceilings.

GROSS WEIGHT

Applicable to: ALL

GENERAL

L2 When the weight increases, the lift must be increased to maintain the altitude. As a result, the drag increases. So, the net thrust must be increased at fixed CAS or Mach.

L1 **FOR A GIVEN HOLDING TIME**

At a fixed pressure altitude, any decrease in weight, due to fuel burn off for example, leads to:
- A lower Fuel Flow (FF)
- A lower THR

L2 The required net thrust decreases.

L1 - Fuel quantity decreases for a given holding time.

FOR A GIVEN HOLDING FUEL

At a fixed pressure altitude, any decrease in weight, due to fuel burn off for example, leads to:
- A lower FF
- A lower THR

L2 The required net thrust decreases.

L1 - Maximum holding time increases for a given fuel quantity
- Distance increases.

L2 The time increases and TAS stays the same.

L1 **HLD**

The flight crew enters the current aircraft weight at start of holding calculation.
This gross weight (GROSS WGHT field) must be between the Operating Empty Weight (OEW) and the Maximum Design Takeoff Weight (MTOW).

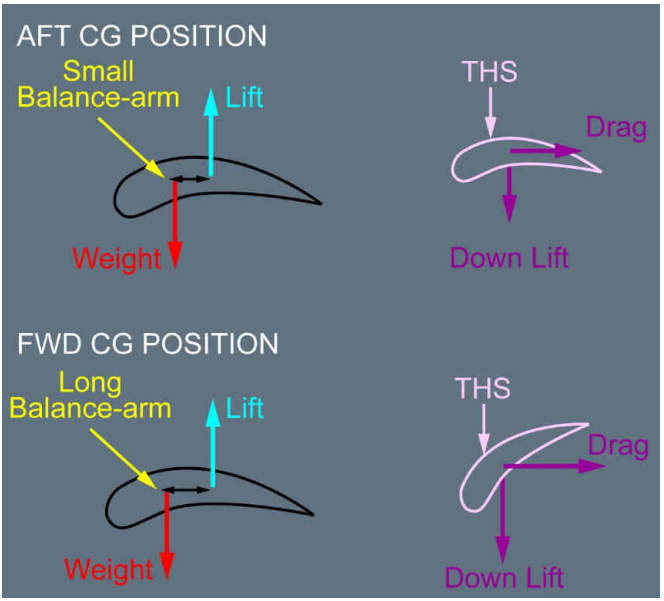
CG

Applicable to: ALL

GENERAL

The Center of Gravity (CG) position impacts the forces applied on the aircraft. As a result, it impacts aircraft performance.

CG Position



L2 In order to keep the aircraft level, the Trimmable Horizontal Stabilizer (THS) creates a downward force that counters the pitch down moment due to the distance between the center of lift and the center of gravity. The larger this lever arm, the higher the down lift that must be generated by the THS, and the higher the drag.

L1 **IN-FLT PERF**

The CG field is expressed in % of the Mean Aerodynamic Chord (MAC).

AIRFLOW

Applicable to: ALL

GENERAL

Airflow increases engine bleed.

L2 The net thrust (which is the thrust necessary to maintain the level flight) stays the same. But, the increased bleed flow leads to an increased Fuel Flow (FF) to generate this thrust.

L1 FOR A GIVEN HOLDING TIME

In the case of an increase in airflow:
- FF increases
- THR increases
- Fuel quantity increases for a given holding time.

FOR A GIVEN HOLDING FUEL

In the case of an increase in airflow:
- FF increases
- THR increases
- Maximum holding time decreases for a given fuel quantity
- Distance decreases.

L2 The time decreases and TAS stays the same.

L1 IN-FLT PERF

IN-FLT PERF has five airflow options:
- OFF
- LO
- MAN
- NORM
- HI.

IMPACT OF FWD CARGO COOLING

When FWD cargo cooling is active, the airflow automatically increases, and so the engine bleed.
The IN-FLT PERF airflow settings reflect the engine bleed with FWD cargo cooling OFF.
The flight crew applies the following equivalences to obtain an engine bleed that considers the effect of FWD cargo cooling:

ENG OPERATIVE	AIR FLOW Selector	FWD Cargo Cooling	Select IN-FLT PERF setting
4	LO	ON	MAN
	MAN		HI
	NORM		HI
	HI		HI
3	LO	ON	MAN
	MAN		MAN
	NORM		NORM
	HI		HI
2	LO	ON	LO
	MAN		MAN
	NORM		NORM
	HI		HI

HOLDING DATA PANEL

Applicable to: ALL

The HOLDING DATA panel describes the following information:

- The Altitude
- The computation type (holding type, holding time, holding fuel)
- The strategy (configuration, speed type, holding pattern)
- The number of engines operative
- The thrust lever position
- The fuel factor.

HOLDING DATA Panel

ALTITUDE

Applicable to: ALL

GENERAL

In level flight at low altitude and at fixed CAS, the net thrust is roughly constant (slight increase with altitude).

L2 The net thrust is the thrust necessary to maintain the level flight.

L1 **FOR A GIVEN HOLDING TIME**

A higher pressure altitude results in:

- A lower Fuel Flow (FF)

L2 At low altitude, the efficiency of the engines is improved when altitude increases.

L1 - A higher THR

L2 The maximum available thrust decreases with altitude and the required net thrust slightly increases.

L1 - Distance increases for a given time

L2 TAS increases for the same CAS.

L1 - Fuel burnt decreases.

FOR A GIVEN HOLDING FUEL

A higher pressure altitude results in:

- A lower FF

L2 At low altitude, the efficiency of the engines is improved when altitude increases.

L1 - A higher THR

L2 The maximum available thrust decreases with altitude and the required net thrust slightly increases.

L1 - Maximum holding time increases for a given fuel quantity

- Distance increases.

L2 The time and TAS increase.

L1 **HLD**

The flight crew enters the holding pressure altitude.

HOLDING TYPE

Applicable to: ALL

The following two computation types are available:

- FUEL, to assess holding fuel for a given holding time
- TIME, to assess maximum holding time capability for a given fuel quantity.

HOLDING STRATEGY

Applicable to: ALL

The HOLDING STRATEGY subpanel describes the following information:

- The configuration (Flaps / Slats)
- The speed type
- The speed increment or speed value (if available)
- The holding pattern.

HOLDING STRATEGY Subpanel

CONFIGURATION

GENERAL

Two aerodynamic configurations are used in operation:
- CLEAN
- 1 when there are limiting obstacles (in terms of holding pattern) around the airport.

HLD

HLD has five options:
- CLEAN
- 1
- 1+F
- 2
- 3
- FULL.

SPEED TYPE

The flight crew uses the SPD TYPE drop-down list to select his holding speed.
The following holding speeds are available:

- CAS

L2 For more information about the CAS type, *Refer to PER-IFT-HLD-HLS CAS* .

L1 - CAS Min Drag

L2 For more information about the CAS Min Drag type, *Refer to PER-IFT-HLD-HLS CAS Min Drag* .

L1 - GD Speed

L2 For more information about the GD Speed type, *Refer to PER-IFT-HLD-HLS GD Speed* .

L1 - S Speed

L2 For more information about the S Speed type, *Refer to PER-IFT-HLD-HLS S Speed* .

L1 - Max End Speed

L2 For more information about the Max End Speed type, *Refer to PER-IFT-HLD-HLS Max End Speed* .

HOLDING PATTERN

The flight crew selects the holding pattern:
- Race track holding, or

L2 A race track pattern is composed of two straight legs plus two 180 degree turns.

L1 - Straight line.

ENGINES OPERATIVE

Applicable to: ALL

GENERAL

The number of engines operative determines the thrust available to perform the holding and therefore impacts holding performance. However, as holding is usually performed at low altitudes and low speeds, the impact is poor.

HLD

The flight crew selects the number of engines operative:
- 4 (ALL), or
- 3, or
- 2.

THRUST

Applicable to: ALL

GENERAL

The thrust available to perform the holding depends on the selected holding rating.
The standard holding rating is called “Maximum Cruise Thrust” which is delivered when the thrust lever is in the CL detent.
However, in the case of an engine failure, the thrust rating “Maximum Continuous Thrust” is mandatory.

L2 For more information, refer to Thrust Ratings.

L1 HLD

The thrust rating is automatically selected, depending on the number of engines operative:
- CL (A/THR), if AEO
- MCT (A/THR), if OEI or TEI.

FUEL FACTOR

Applicable to: ALL

GENERAL

The performance factor for FMS predictions (FMS PERF FACTOR) is the sum of the Basic FMS PERF FACTOR and the Monitored Fuel Factor.

BASIC FMS PERF FACTOR

The Basic FMS PERF FACTOR correction is applied when the aircraft FMS database does not exactly fit to the aircraft model. It is published for each FMS Performance Data Base (PDB).
It results in FMS predictions consistent with the level reflected by the uncorrected IN-FLT PERF application, also called the book level.

MONITORED FUEL FACTOR

The actual airframe drag and engine performance deviate from the nominal model due to the aircraft's aging process.
The Monitored Fuel Factor is used to correct the performance book level to the actual performance level in order to permit realistic fuel predictions.
The Monitored Fuel Factor is defined as a percentage increase or decrease of the nominal Specific Range (SR) value.

IN-FLT PERF

The IN-FLT PERF fuel factor corresponds to the sum of:
- The Monitored Fuel Factor, and
- A positive performance prediction adjustment (if enabled, and at flight crew discretion).

L2 This allows the flight crew to adjust performance predictions to a drag increase due to non-quantified aerodynamic sources.

L1 When no such performance adjustment is required, the IN-FLT PERF fuel factor may thus differ from the FMS one by the Basic FMS PERF FACTOR.

CAS

Applicable to: ALL

The flight crew may use the CAS speed type to calculate holding performance for a holding in selected speed/Mach target, at fixed CAS, and usually with:

- 240 kt for CONF 1
- 210 kt for CONF 2.

CAS MIN DRAG

Applicable to: ALL

The flight crew may use the CAS Min Drag speed type to calculate holding performance for a holding in selected speed/Mach target, at CAS Min Drag, and for CONF CLEAN or 1.

This is flown by manually setting the CAS Min Drag on the AFS CP, computed by the CAS Min Drag speed type.

The CAS Min Drag speed type gives an average value of CAS Min Drag during the holding phase.

GD SPEED

Applicable to: ALL

L2 The maximum holding time (maximum endurance) is a determining factor for a holding. This may be done by minimizing the Fuel Flow (FF). The corresponding speed (maximum endurance speed) is close to green dot speed + 25 kt.

L1 In CONF CLEAN, the standard holding speed is the green dot speed + 25 kt.

The flight crew may use the GD Speed speed type with green dot speed + 25 kt to calculate holding performance for a holding in managed speed/Mach target, at maximum endurance speed, and in CONF CLEAN.

The flight crew may also use the GD Speed speed type to calculate holding performance for a holding in selected speed/Mach target, at green dot speed, and in CONF CLEAN. This is flown by manually setting the green dot speed on the AFS CP, computed by the FMC based on aircraft weight, and indicated on the PFD.

The GD Speed speed type gives an average value of green dot speed during the holding phase.

S SPEED

Applicable to: ALL

L2 Holding patterns at green dot speed may be limiting in CONF CLEAN. In fact, obstacles nearby some airports can bring about significant bank angles during turn phase. As it is not preferable to fly below green dot speed in CONF CLEAN, slats may be extended and holding done in CONF 1 at S Speed.
For more information about S Speed, *Refer to DSC-22-27-10-10 GREEN DOT* .

L1 The flight crew may use the S Speed speed type to calculate holding performance for a holding in selected speed/Mach target, at S Speed, and in CONF 1.
This is flown by manually setting S on the AFS CP , computed by the FMC based on aircraft weight, and indicated on the PFD .
The S Speed speed type gives an average value of S during the holding phase.

MAX END SPEED

Applicable to: ALL

L2 The maximum holding time (maximum endurance) is a determining factor for a holding. This may be done by minimizing the Fuel Flow (FF). The corresponding speed is the maximum endurance speed.

L1 The flight crew may use the Max End Speed speed type to calculate holding performance for a holding in managed speed/Mach target in CONF CLEAN.
In managed speed/Mach target in CONF CLEAN, the holding speed targeted by the FMS is the maximum endurance speed.

DISTANCE

Applicable to: ALL

In the case of a straight line holding, the RESULTS panel shows the ground distance covered:
- For a given holding time, or
- For a given holding fuel quantity.

FUEL

Applicable to: ALL

The RESULTS panel displays the fuel quantity (FUEL) used, which corresponds to:
- The fuel burnt during the given holding time, or
- The holding fuel quantity entered by the flight crew.

FUEL FLOW

Applicable to: ALL

GENERAL

The Fuel Flow (FF) is defined as the fuel consumption per time unit.

HLD

The RESULTS panel shows:
- The average total FF during the holding phase
- The average FF per engine during the holding phase.

AVERAGE CAS SPEED

Applicable to: ALL

The RESULTS panel shows the average CAS speed during the holding phase.

THR

Applicable to: ALL

GENERAL

The THR value indicates the thrust used. It is shown as a % of the available thrust.

Assuming that the thrust achieved in windmilling is close to zero, the available thrust is the ratio of the actual thrust calculated from engine parameters to:

- The thrust achieved with TO thrust rating and bleeds OFF for Takeoff and Taxi
- The thrust achieved with GA thrust rating and bleeds OFF for all other flight phases (Climb, Cruise, Descent, Holding).

HLD

The RESULTS panel shows the average THR during the holding phase.

FINAL WEIGHT

Applicable to: ALL

The RESULTS panel displays the final weight (FINAL WGHT) of the aircraft at the end of the holding phase.

MAXIMUM HOLDING TIME

Applicable to: ALL

The RESULTS panel shows the maximum holding time, which corresponds to:

- The holding time entered by the flight crew, or
- The maximum endurance for a given holding fuel quantity.

GENERAL

Applicable to: ALL

The flight crew may use the performance data calculated with the IN-FLT PERF to conduct and monitor a flight after an engine failure.

DIVERSION STRATEGY

Applicable to: ALL

The diversion strategy (climb, descent and cruise speed schedules) shall be defined before the flight, and described in the Operator's routes specifications, as a function of the prevailing operational factors (e.g. obstacles clearance requirements).
If there are constraining obstacles along the route, the OBSTACLE strategy must be selected.
Otherwise, the STANDARD strategy is recommended.

Intentionally left blank

SEVERE ICING

Applicable to: ALL

If severe icing conditions are encountered, ice may build up on non heated structure. In these conditions:

- The minimum speed is Green Dot in clean configuration
- The nominal gross OEI Level off is reduced by 5 000 ft.

L2 The nominal gross Level off is calculated at Green Dot speed, engines at MCT, Anti-ice Off. The reduction in altitude takes into account of the effect of activation of Anti-ice Total and ice accretion.

Intentionally left blank

EO Below EO MAX Altitude

BELOW EO MAX ALTITUDE

Applicable to: ALL

ENGINE FAILURE BELOW EO MAX ALTITUDE

DRIFT UP

As there are constraining obstacles along the route, a drift up at green dot speed is performed to clear the obstacles.

The drift up is operated either:
- In selected speed/Mach target at green dot speed with thrust lever in the MCT detent and A/THR disconnected, or
- In managed speed/Mach target with thrust lever in the MCT detent following to the FMS EO - GDOT function.

For more information about the IN-FLT PERF predictions for the drift up phase, *Refer to PER-IFT-OEI-OBS-BLW Drift Up - Green Dot Speed* .

DESCENT TO EO MAX ALTITUDE

As soon as obstacles are cleared, a standard descent is performed to the new cruise altitude at most equal to EO MAX altitude.
For more information about the IN-FLT PERF predictions for this phase common with the STANDARD strategy, *Refer to PER-IFT-OEI-STD-ABV Descent to EO MAX Altitude* .

CRUISE TO DIVERSION AIRPORT

A cruise is initiated to reach a diversion airport.

The cruise phase is operated either:
- In selected speed/Mach target at LRC speed with A/THR engaged, or
- In managed speed/Mach target.

For more information about the IN-FLT PERF predictions for this phase common with the STANDARD strategy, *Refer to PER-IFT-OEI-STD-ABV Descent to EO MAX Altitude* .

DESCENT TO LANDING

The descent to the diversion airport is operated either:
- In selected speed/Mach target with a given fixed speed schedule (M 0.85 /300 kt /250 kt) and A/THR engaged, or
- In managed speed/Mach target.

DRIFT UP - GREEN DOT SPEED

Applicable to: ALL

The flight crew may use the IN-FLT PERF Best angle climb type to calculate EO climb performance for the drift up phase of the OBSTACLE strategy with EO below EO MAX altitude.

This is flown in selected speed/Mach target by manually setting the green dot speed on the AFS CP computed by:

- The FMC based on aircraft weight, and indicated on the PFD and the MFD PERF CLB page (MAX ANGLE function), or
- The IN-FLT PERF Best angle climb type.

Moreover, this is usually flown in managed speed/Mach target (EO-GDOT function).

EO Above EO MAX Altitude

ABOVE EO MAX ALTITUDE

Applicable to: ALL

EO IN CRUISE OR IN CLIMB

DECELERATION

After the engine failure, a deceleration phase in level flight is initiated to green dot speed.
The thrust lever is set in the MCT detent with A/THR disconnected.

DRIFT DOWN

As there are constraining obstacles along the route, a drift down is performed to clear the obstacles.
The drift down is operated at green dot speed.
The thrust lever is still in the MCT detent with A/THR disconnected.
If there are still constraining obstacles on the route once the level off is reached, the drift down must be maintained so as to fly an ascending cruise profile.
For more information about the IN-FLT PERF predictions for the drift down phase, *Refer to PER-IFT-OEI-OBS-ABV Drift Down - Green Dot* .

DESCENT TO EO MAX ALTITUDE

As soon as obstacles are cleared, a standard descent is performed to the new cruise altitude at most equal to EO MAX altitude.
For more information about the IN-FLT PERF predictions for this phase common with the STANDARD strategy, *Refer to PER-IFT-OEI-STD-ABV Descent to EO MAX Altitude* .

CRUISE TO DIVERSION AIRPORT

A cruise is initiated to reach a diversion airport.

The cruise phase is operated either:
- In selected speed/Mach target at LRC speed with A/THR engaged, or
- In managed speed/Mach target.

For more information about the IN-FLT PERF predictions for this phase common with the STANDARD strategy, *Refer to PER-IFT-OEI-STD-ABV Descent to EO MAX Altitude* .

DESCENT TO LANDING

The descent to the diversion airport is operated either:
- In selected speed/Mach target with a given fixed speed schedule (M 0.85 /300 kt /250 kt) and A/THR engaged, or
- In managed speed/Mach target.

DRIFT DOWN - GREEN DOT

Applicable to: ALL

The flight crew may use the OBSTACLE Green Dot descent type to calculate EO descent performance for the drift down phase of the OBSTACLE strategy with EO above EO MAX altitude (green dot speed and thrust lever in the MCT detent with A/THR disconnected).

This is flown in selected speed/Mach target by manually setting the green dot speed on the AFS CP computed by:

- The FMC based on aircraft weight, and indicated on the PFD, or
- The IN-FLT PERF OBSTACLE Green Dot descent type.

DRIFT DOWN - FIXED SPEED

Applicable to: ALL

The flight crew may use the OBSTACLE Fixed Speed descent type to calculate EO descent performance for a descent in selected speed/Mach target with a given fixed speed schedule, and thrust lever in the MCT detent with A/THR disconnected.
The OBSTACLE Fixed Speed descent type is an alternative to OBSTACLE Green Dot. However, contrary to Green Dot, Fixed Speed does not permit the aircraft to maintain the highest possible level.

Intentionally left blank

EO Below EO MAX Altitude

EO BELOW EO MAX ALTITUDE

Applicable to: ALL

ENGINE FAILURE BELOW EO MAX ALTITUDE

CLIMB TO EO MAX ALTITUDE

As there are no constraining obstacles along the route, the climb proceeds up to a new cruise altitude, which is at or below the EO MAX altitude.

After the engine failure, the climb is operated either:
- In selected speed/Mach target with thrust lever in the MCT detent and A/THR disconnected, or
- In managed speed/Mach target with thrust lever in the MCT detent following to the FMS EO - GDOT function.

For more information about the IN-FLT PERF predictions for the climb to EO MAX altitude phase, *Refer to PER-IFT-OEI-STD-BLW Climb to EO MAX Altitude* .

CRUISE TO DIVERSION AIRPORT

A cruise is initiated to reach a diversion airport.

The cruise phase is operated either:
- In selected speed/Mach target at LRC speed with A/THR engaged.
- In managed speed/Mach target.

For more information about the IN-FLT PERF predictions for the cruise phase to diversion airport, *Refer to PER-IFT-OEI-STD-ABV Cruise to Diversion Airport* .

DESCENT TO LANDING

The descent to the diversion airport is operated either:
- In selected speed/Mach target with a given fixed speed schedule (M 0.85 /300 kt /250 kt) and A/THR engaged, or
- In managed speed/Mach target.

CLIMB TO EO MAX ALTITUDE

Applicable to: ALL

The flight crew may use the IN-FLT PERF Selected speeds climb type to calculate EO climb performance at a given fixed speed schedule for the climb to EO MAX altitude phase of the STANDARD strategy with EO below EO MAX altitude.

EO Above EO MAX Altitude

EO ABOVE EO MAX ALTITUDE

Applicable to: ALL

EO IN CRUISE OR IN CLIMB ABOVE EO MAX ALTITUDE

DECELERATION

After the engine failure, a deceleration phase in level flight is initiated to a speed not below green dot.
The thrust lever is set in the MCT detent with A/THR disconnected.

DESCENT TO EO MAX ALTITUDE

As there are no constraining obstacle along the route, a standard descent is performed to the new cruise altitude at most equal to EO MAX altitude.
The descent is operated with a given fixed speed schedule (M 0.85 /300 kt). The thrust lever is still in the MCT detent with A/THR disconnected.
If ROD becomes less than 500 ft/min , the flight crew must engage the basic vertical mode V/S on the AFS CP with a ROD value of 500 ft/min . The A/THR is activated.
For more information about the IN-FLT PERF predictions for the descent phase to EO MAX altitude, *Refer to PER-IFT-OEI-STD-ABV Descent to EO MAX Altitude* .

CRUISE TO DIVERSION AIRPORT

A cruise is initiated to reach a diversion airport.

The cruise phase is operated either:
- In selected speed/Mach target at LRC speed with A/THR engaged.
- In managed speed/Mach target.

For more information about the IN-FLT PERF predictions for the cruise phase to diversion airport, *Refer to PER-IFT-OEI-STD-ABV Cruise to Diversion Airport* .

DESCENT TO LANDING

The descent to the diversion airport is operated either:
- In selected speed/Mach target with a given fixed speed schedule (M 0.85 /300 kt /250 kt) and A/THR engaged, or
- In managed speed/Mach target.

DESCENT TO EO MAX ALTITUDE

Applicable to: ALL

The flight crew may use the DES EO-STD Mach/CAS - V/S descent type to calculate EO descent performance for the descent to EO MAX altitude phase of:

- The STANDARD strategy with EO above EO MAX altitude, or
- The OBSTACLE strategy.

This is flown in selected speed/Mach target by manually setting M 0.85 /300 kt on the AFS CP (with thrust lever in the MCT detent and A/THR disconnected).
And when the Rate of Descent (ROD) becomes less than 500 ft/min, this strategy is flown by engaging the basic vertical mode V/S on the AFS CP with a ROD value of 500 ft/min (with thrust lever in the MCT detent and A/THR activated).

CRUISE TO DIVERSION AIRPORT

Applicable to: ALL

The flight crew may use the IN-FLT PERF LRC Speed or ECON (CI) cruise types to calculate EO cruise performance for the cruise phase to diversion airport of:
- The STANDARD strategy, or
- The OBSTACLE strategy.

LRC SPEED

The flight crew may use the IN-FLT PERF LRC Speed cruise type to obtain current and predicted cruise performance data for a cruise to diversion airport at EO LRC speed.
This is flown in selected speed/Mach target by manually setting the EO LRC speed on the AFS CP computed by the IN-FLT PERF LRC Speed cruise type.

L2 Engine Out Long Range Cruise (EO LRC) speed is defined as the Mach for which the Specific Range (SR) is equal to 99 % of the maximum SR with one engine inoperative.

EO LRC Mach depends on:
- Cruise altitude
- Weight
  The EO LRC Mach increases when weight increases.
- Temperature
  The EO LRC Mach decreases when temperature increases.
- Wind
  The EO LRC Mach increases when headwind increases.
- Air flow and anti-ice.

L1 ECON (CI)

If the flight crew selects a number of engines less than 4 and the IN-FLT PERF ECON (CI) cruise type, the application will prompt the flight crew whether he wants to perform a computation with the EO CI_{LRC} or with the current CI value.

The IN-FLT PERF ECON (CI) cruise type enables the flight crew to emulate several MFD CRZ page predictions:
- EO MAX altitude
- ECON Mach.

The flight crew may use the IN-FLT PERF ECON (CI) cruise type to obtain current and predicted cruise performance data for a cruise to diversion airport in managed speed/Mach target following to:
- The FMS EO-LRC function, or
- The FMS EO-ECON function.

EO-LRC

The FMS EO-LRC function (in managed speed/Mach target) ensures a longer range with OEI by optimizing the CI.

This function uses a specific value of CI called Engine Out Cost Index Long Range (EO CI $_{LRC}$).

L2 EO CI $_{LRC}$ is defined as the CI value which approximates the Long Range Cruise (LRC) with one engine inoperative.

EO CI $_{LRC}$ = 65.

L1 EO-ECON

The FMS EO-ECON function (in managed speed/Mach target) can be used if there is a sufficient FOB quantity to reach the diversion airport with the AEO CI.

This function uses the AEO CI value which was entered by the flight crew for the flight.

PLAN - In Cruise

GENERAL

Applicable to: ALL

The PLAN module does not allow the flight crew to compute an EO diversion from the engine failure point.
However, the PLAN module may enable the flight crew to assess the EO diversion fuel and time from the start of the cruise to diversion airport phase.

ECON (CI)

Applicable to: ALL

An IN CRUISE ECON (CI) EO planning is divided into three main flight phases:

- An ECON (CI) cruise phase following:
  - The EO-LRC function (EO CI $_{LRC}$), or
  - The EO-ECON function (current CI).
- An ECON (CI) descent, with the following descent law:
  - ECON descent Mach, which is the ECON cruise Mach at T/D
  - ECON descent CAS, which is a function of on CI, gross weight at T/D, cruise altitude
  - 250 kt from 10 000 ft to 1 500 ft.
- A standard approach and landing.

LRC SPEED

Applicable to: ALL

An IN CRUISE LRC Speed EO planning is divided into three main flight phases:

- A cruise phase at EO LRC speed
- A descent at standard descent speed profile
- A standard approach and landing.

Intentionally left blank

GD SPEED

Applicable to: ALL

In CONF CLEAN, the standard EO holding speed is the green dot +25 kt.
The flight crew may use the GD Speed speed type with green dot speed + 25 kt to calculate holding performance for a holding in managed speed/Mach target, at maximum endurance speed, and in CONF CLEAN.
The GD Speed speed type gives an average value of green dot speed during the holding phase.

Intentionally left blank

LRC - OPTIMUM ALTITUDE

Applicable to: ALL

An ALTERNATE LRC Speed planning at initial optimum altitude is divided into five flight phases:

- A standard missed approach (go-around)
- A climb at standard climb speed profile
- A cruise phase at the initial optimum altitude and conducted in selected speed/Mach target at EO LRC speed
- A descent at standard descent speed profile
- A standard approach and landing.

LRC - INPUT ALTITUDE

Applicable to: ALL

An ALTERNATE LRC Speed planning at input cruise altitude is divided into five flight phases:

- A standard missed approach (go-around)
- A climb at standard climb speed profile
- A cruise phase at the input cruise altitude and conducted in selected speed/Mach target at EO LRC speed
- A descent at standard descent speed profile
- A standard approach and landing.

Intentionally left blank

GENERAL

Applicable to: ALL

The flight crew may use the performance data calculated with the IN-FLT PERF to conduct and monitor a flight after a second engine failure.

Intentionally left blank

SEVERE ICING

Applicable to: ALL

If severe icing conditions are encountered, ice may build up on non heated structure. In these conditions:

- The minimum speed is Green Dot in clean configuration
- The nominal gross TEI Level off is reduced by 5 000 ft.

L2 The nominal gross Level off is calculated at Green Dot speed, engines at MCT, Anti-ice Off. The reduction in altitude takes into account of the effect of activation of Anti-ice Total and ice accretion.

Intentionally left blank

GENERAL

Applicable to: ALL

DESCENT TO LEVEL OFF

A descent at green dot speed is performed down to the level off. The thrust lever is set in the MCT detent with A/THR disconnected.
For more information about the IN-FLT PERF predictions for the descent phase to level off, *Refer to PER-IFT-TEI-STD Descent to Level Off* .

CRUISE TO DIVERSION AIRPORT

After level off, the altitude is maintained.
A cruise phase is operated in selected speed/Mach target at LRC speed.
For more information about the IN-FLT PERF predictions for the cruise phase to diversion airport, *Refer to PER-IFT-TEI-STD Cruise to Diversion Airport* .

DESCENT TO LANDING

The descent to the diversion airport is operated in selected speed/Mach target with a given fixed speed schedule (300 kt /250 kt) and A/THR engaged.

DESCENT TO LEVEL OFF

Applicable to: ALL

The flight crew may use the OBSTACLE Green Dot descent type to calculate TEO descent performance according to the STANDARD strategy (green dot speed and thrust lever in the MCT detent with A/THR disconnected).

This is flown in selected speed/Mach target by manually setting the green dot speed on the AFS CP computed by:
- The FMC based on aircraft weight, and indicated on the PFD, or
- The IN-FLT PERF OBSTACLE Green Dot descent type.

CRUISE TO DIVERSION AIRPORT

Applicable to: ALL

The flight crew may use the IN-FLT PERF LRC Speed cruise type to obtain current and predicted cruise performance data for a cruise at TEO LRC speed.
This is flown in selected speed/Mach target by manually setting the TEO LRC speed on the AFS CP computed by the IN-FLT PERF LRC Speed cruise type.
TEO LRC speed is defined as the Mach for which the SR is equal to 99 % of the maximum SR with two engines inoperative.

TEO LRC speed depends on:
- Cruise altitude
- Weight

L2 The LRC Mach increases when weight increases.

L1 - Temperature

L2 The LRC Mach decreases when temperature increases.

L1 - Wind

L2 The LRC Mach increases when headwind increases.

L1 - Air flow and Anti-ice.

IN CRUISE - LRC SPEED

Applicable to: ALL

An IN CRUISE LRC Speed TEO planning is divided into three main flight phases:
- A cruise phase at TEO LRC speed
- A descent at standard descent speed profile
- A standard approach and landing.

GD SPEED

Applicable to: ALL

In CONF CLEAN, the standard TEO holding speed is the green dot.
The flight crew may use the GD Speed speed type to calculate holding performance for a holding in selected speed/Mach target, at green dot speed, and in CONF CLEAN.
This is flown by manually setting the green dot speed on the AFS CP, computed by the FMC based on aircraft weight, and indicated on the PFD.
The GD Speed speed type gives an average value of green dot speed during the holding phase.

Intentionally left blank

AIRCRAFT STATUS PANEL

Applicable to: ALL

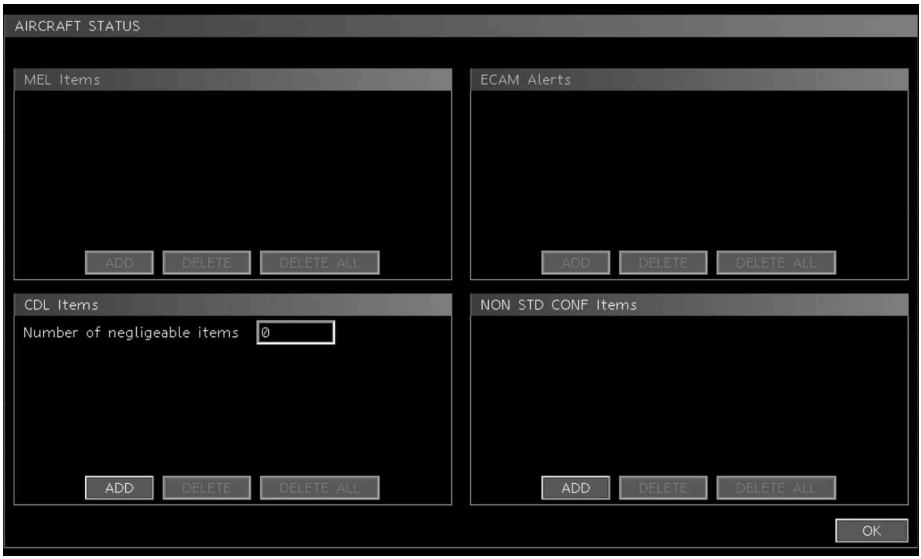
The current aircraft status must be considered for the computation.
The reminder area of the AIRCRAFT STATUS panel lists CDL items and Non Standard Configuration (NON STD CONF) items that have an impact on in-flight performance.
If no CDL /NON STD CONF item that affects in-flight performance is selected, "normal" appears in the reminder area of the AIRCRAFT STATUS panel.

Reminder area of the AIRCRAFT STATUS Panel

By clicking on the ACFT STS button, the flight crew opens the AIRCRAFT STATUS panel.

The AIRCRAFT STATUS panel is divided in four subpanels:
- MEL Items
- CDL Items
- ECAM Alerts
- NON STD CONF Items.

AIRCRAFT STATUS Panel



NON STD CONF

Applicable to: ALL

The NON STD CONF Items subpanel displays the non-standard configurations selected by the flight crew.
To open the NON STD CONF Items panel, the flight crew uses the ADD button of the NON STD CONF Items subpanel . The NON STD CONF Items panel displays the list of non-standard configurations that affect the in-flight computation and that involve in-flight performance penalties (e.g. fuel consumption increase, altitude restriction, speed limitation).

NON STD CONF Items Panel

To add a non-standard configuration item, the flight crew selects the appropriate status for each item in the drop-down lists.
The selected items appears in the NON STD CONF Items subpanel and in the reminder area of the AIRCRAFT STATUS panel.

FLAPS / SLATS

The flight crew defines the aircraft aerodynamic configuration if this one is different from CLEAN.
The FLAPS / SLATS item is not available in the HLD module (standard configuration).

SPD BRK

The flight crew selects EXTENDED if the speed brakes are extended.
The SPD BRK item is disabled in the CLB module.
The SPD BRK item is not available in the DES module (standard configuration).

ENG INOPERATIVE STS

The flight crew selects FAN BLDS REMOVD if the aircraft is dispatched with three engines ferry flight and in core blank configuration.
For more information about the three engines ferry flight speed profile, *Refer to Three Engines Ferry Flight Procedure - Performance Data* .

L/G

The flight crew selects EXTENDED in the case of L/G RETRACTION FAULT.
For more information about the L/G RETRACTION FAULT procedure, *Refer to PRO-ABN-ECAM-10-32-70 L/G RETRACTION FAULT* .
The flight crew select DISPATCH WITH GEAR DOWN if the aircraft is dispatched with landing gear down and the gear doors closed.
For more information about the dispatch with gear down, *Refer to Flight With Gear Down* .

Note: *In the CRZ module and the PLAN module, do not use a Mach number speed input for a computation with L/G EXTENDED or DISPATCH WITH GEAR DOWN.*
Workaround: Enter the speed input directly in CAS .

L/G DOORS

The flight crew selects OPEN in the case of L/G DOORS NOT CLOSED.
For more information about L/G DOORS NOT CLOSED, *Refer to PRO-ABN-ECAM-10-32-80 L/G DOORS NOT CLOSED* .

Note: *In the CRZ module and the PLAN module, do not use a Mach number speed input for a computation with L/G DOORS OPEN.*
Workaround: Enter the speed input directly in CAS .

PRESSURIZATION

The fight crew selects DISPATCH WITHOUT in the case of a flight without cabin pressurization.
For more information about a flight without cabin pressurization, *Refer to Flight Without Cabin Pressurization - Overview* .

MEL

Applicable to: ALL

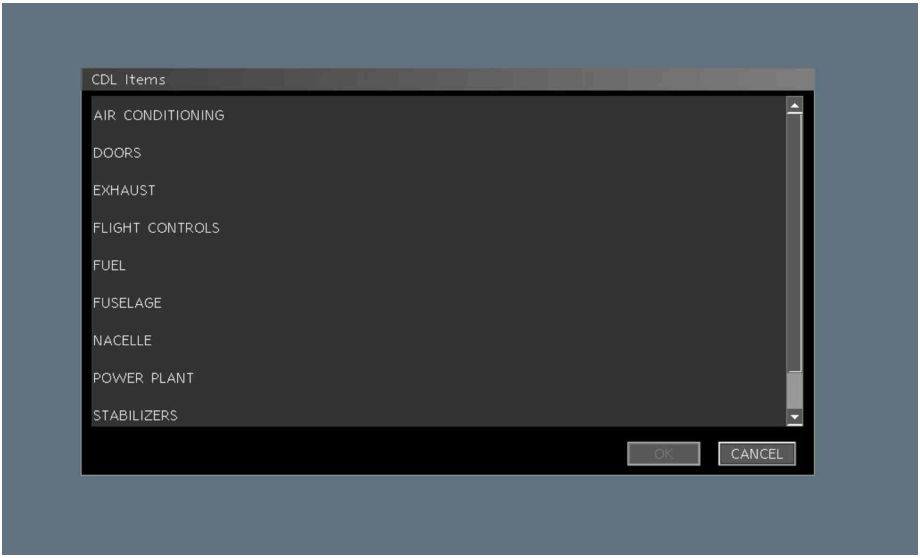
This function is not available yet.

CDL

Applicable to: ALL

The CDL Items subpanel displays the number of negligible items. Depending on this number, penalties will be applied for the in-flight computation.
By clicking on the ADD button of the CDL Items subpanel, the flight crew opens the CDL Items panel.
The CDL Items panel displays the list of structural parts that could be missing. These items involve performance penalties.

CDL Items Panel



The flight crew selects a CDL item by first selecting the applicable system, and then the corresponding failure case. The flight crew must enter the appropriate number of items that are missing.
Items selected from the lists on the CDL Items panel appears in the CDL Items subpanel and in the reminder area of the AIRCRAFT STATUS panel.

IN-FLT PERF does not include the following CDL items affecting high speed performance:
- 27-03 Slat Blade Seal
- 27-05 Aileron End Seal
- 27-14 Droop Nose Blade Seal
- 54-02 Pylon Apron Seal
- 57-06 Seal of FTE lower panel to flap.

For these CDL items, the flight crew must manually:

- Enter the fuel consumption penalty published in the OPS LIBRARY / CDL manual into the FUEL FACTOR field
- Reduce the computed ceilings by the en-route performance altitude penalty available in the OPS LIBRARY / CDL manual
  The flight crew can use the following conversion rate from the published weight penalty to the ceiling penalty: 10 kg corresponds to 1 ft.

Note: *Ticked CDL items from the AFM are not transferred to the IN-FLT PERF application. The flight crew must select directly the CDL items in the IN-FLT PERF application*

Intentionally left blank

GENERAL

Applicable to: ALL

The FMS predictions do not consider the over consumption resulting from any failure except the engine one.
In the case of a failure leading to an increase in the fuel consumption, the ECAM STATUS page displays "FUEL CONSUMPT INCRSD : FMS PRED DISREGARD".
Therefore, the flight crew can use IN-FLT PERF to assess this over consumption by selecting the corresponding ECAM Alerts item.

IMPACT ON INPUT

Applicable to: ALL

When the flight crew selects an ECAM Alerts item, the CLB, DES and ATMO modules are disabled.

The flight crew can perform CRZ, HLD, and PLAN computations:
- With only one ECAM Alerts item
- With all engine operative
- With the following fixed state of the Non Standard Configuration items:
  - FLAPS / SLATS: CLEAN
  - SPD BRK: RETRACTED
  - 1 ENG OUT FERRY FLIGHT: NO
  - L/G: RETRACTED
  - L/G DOORS: CLOSED

Only the IN CRUISE computation type is enabled for PLAN computation.

IMPACT ON RESULTS

Applicable to: ALL

The selection of an ECAM Alerts item modifies the RESULTS panel.
The label “IN-FLIGHT FAILURE SELECTED” appears in red on the RESULTS panel.
All the results parameters consider the effect of the selected ECAM Alerts item.

CRZ MODULE

FUEL

The FUEL panel displays an additional parameter named PERF FACTOR WITH FAILURE.
If the flight crew selects an ECAM Alerts item, IN-FLT PERF optimizes the associated fuel penalty depending on the flight conditions, contrary to the FCOM envelope fuel penalties that are conservatives.
This associated fuel penalty factor is named Performance Factor With Failure (LPFC).
LPFC is computed using the worse possible state of the failure. Therefore, the flight crew should adjust the LPFC value during the flight, via an appropriate in-flight fuel check.

ALT

The STEP TO field disappears.

MORE PANEL

LPFC is added in the TABLE results and in the GRAPH results.

HLD MODULE

The RESULTS panel displays an additional parameter named Average PERF FACTOR WITH FAILURE.
If the flight crew selects an ECAM Alerts item, IN-FLT PERF optimizes the associated fuel penalty depending on the flight conditions, contrary to the FCOM envelope fuel penalties that are conservatives.
This associated fuel penalty factor is named Performance Factor With Failure (LPFC).
LPFC is computed using the worse possible state of the failure. Therefore, the flight crew should adjust the LPFC value during the flight, via an appropriate in-flight fuel check.
The HLD module displays an average LPFC along the holding phase.

PLAN MODULE

The MORE panel disappears. There are no more TABLE results and GRAPH results.

The PLAN module automatically computes and displays two types of results:
- Fuel, time and air distance at current conditions without In-Flight Failure

- Fuel, time and air distance at current conditions with the selected In-Flight Failure (with the ECAM Alerts item selected by the flight crew)

The RESULTS panel also displays an additional parameter named AVERAGE FUEL PENALTY FACTOR.
If the flight crew selects an ECAM Alerts item, IN-FLT PERF optimizes the associated fuel penalty depending on the flight conditions, contrary to the FCOM envelope fuel penalties that are conservatives.
This associated fuel penalty factor is named Performance Factor With Failure (LPFC).
LPFC is computed using the worse possible state of the failure. Therefore, the flight crew should adjust the LPFC value during the flight, via an appropriate in-flight fuel check.
The PLAN module displays an average LPFC along the trip.

LANDING PERFORMANCE CALCULATION

Applicable to: ALL

The landing performance calculation determines the Maximum Landing Weight Limited by the Performance (MLW(PERF)).

The landing performance calculation checks that the aircraft can land at destination in compliance with the regulatory requirements.

The landing performance is calculated for each runway, the aircraft settings (flaps, air conditioning and anti-ice selection), the outside conditions (temperature, wind and QNH), and the go-around gradient.

LDG PERF COMPUTATION

Applicable to: ALL

The Landing Performance Application (LDG PERF) provides the performance information to the flight crew for landing.

The flight crew uses LDG PERF:

- In DISPATCH computation type, to determine the MLW(PERF) during the flight preparation
- In IN-FLIGHT computation type, to check during the flight the landing performance in the case of a significant change of the conditions since the dispatch.

L2 The significant change may be a failure occurring during the flight, a change in the weather conditions or a change of the runway in use.

L1 MLW(PERF)

To calculate the MLW(PERF), the flight crew enters the forecasted conditions at destination and may use the certified MLW for Landing Weight (LW) input.

Note: Even if MLW(PERF) is more than the certified MLW , the aircraft must be dispatched with a landing weight below the certified MLW .

When the MLW(PERF) is below the LW value entered by the flight crew, LDG PERF displays the labels "- - -" instead of some output values.

LANDING DATA

To calculate the landing data, the flight crew enters the forecasted conditions and aircraft weight. LW input must be below or equal to MLW(PERF).

OVERWEIGHT LANDING

The overweight landing calculation is only available in In-Flight computation type. In the case of an overweight landing, the flight crew enters a LW above the certified MLW , which must be below the certified MTOW .

L2 For more information about the overweight landing procedure, *Refer to PRO-ABN-ECAM-10-80-50 MISC OVERWEIGHT LDG* .

LDG PERF PARAMETERS

Applicable to: ALL

INPUT PARAMETERS

LDG PERF uses the following landing performance parameters:

- The characteristics of the runway

L2
- Landing Distance Available (LDA)
- Elevation
- Slope.

For more information about the characteristics of the runway, *Refer to PER-LND-LCD-RWY Airport Panel* .

L1 - The outside conditions

L2
- Temperature
- Wind
- Sea level atmospheric pressure (QNH)
- Anti-ice
- Runway state.

For more information about the outside conditions, *Refer to PER-LND-LCD-OCD Outside Conditions Subanel* .

L1 - The aircraft configuration

L2
- Landing Weight (LW)
- Aerodynamic configuration
- Air conditioning
  The flight crew may improve go-around performance by selecting air conditioning OFF.
- Aircraft CG position.
- Approach speed

For more information about the aircraft configuration, *Refer to PER-LND-LCD-ACC Aircraft Configuration Subpanel* .

L1 - The aircraft status.

L2
- Configuration Deviation List (CDL)
- Minimum Equipment List (MEL)
- ABNORMAL & EMERGENCY (ABNEMER) Configuration (for in-flight computation only).

For more information about the aircraft status in dispatch, *Refer to PER-LND-LCD-AFS AIRCRAFT STATUS Panel* .
For more information about the aircraft status in flight, *Refer to PER-LND-LCF-AFS AIRCRAFT STATUS Panel* .

L1 OUTPUT PARAMETERS

LDG PERF provides the following results:

- The approach and go-around speeds and the speed increments

L2
- Go-around speed
- VAPP (for in-flight computation only)
- Vref (for in-flight computation only)
- Vpilot (for in-flight computation only)
- Wind speed increment (for in-flight computation only)
- Failure speed increment (for in-flight computation only).

For more information about these speeds, *Refer to PER-LND-LRF-FSR Landing Speed* .

L1 - The aircraft data

L2
- Flaps
- Go-around gradient
- Landing Weight (LW)
- Maximum Landing Weight Limited by Performance (MLW(PERF)).

For more information about the landing weights, *Refer to PER-LND-LRD-DSR Landing Weights* .

L1 - The limitations

L2 For more information about the landing limitation codes, *Refer to PER-LND-LRD-DSR Landing Limitation Codes* .

L1 - The landing distances.

L2
- Landing Distance (LD)
  For more information about the LD in dispatch, *Refer to PER-LND-LRD-DSR Landing Distances* .
  For more information about the LD in flight, *Refer to PER-LND-LRF-FSR Landing Distances* .
- Stop margin (for in-flight computation only).
  For more information about the Stop margin, *Refer to PER-LND-LRF-FSR Stop Margin* .

LANDING DISTANCE DEFINITIONS

Applicable to: ALL

ACTUAL LANDING DISTANCE

The Actual Landing Distance (ALD) is the distance covered from a point at which the aircraft is 50 ft above the runway threshold to a full stop.

The calculation of the ALD considers that:

- The approach speed is:
  - VLS for manual landing, or
    VLS is equal to 1.23 VS1G of the current flaps setting. L2
  - VLS + 5 kt for CAT II / CAT III automatic landing. L1

  Note: Landing should be calculated at least at VLS + 5 kt when the approach is planned with the use of A/THR.

- The flight crew applies maximum braking at the main gear touchdown
- The antiskid system is operating
- The ground spoilers are operating
- The thrust reversers selection is possible depending on the Operator's policy, except on dry runways.

REQUIRED LANDING DISTANCE

MANUAL LANDING

On a dry runway, the Required Landing Distance (RLD) is the ALD divided by 0.6.
On a wet runway, the RLD is the RLD calculated for the dry runway multiplied by 1.15.

For EU OPS and JAR OPS operators, on a contaminated runway, the RLD is the greater of:

- The RLD calculated on wet runway
- The ALD calculated on the contaminated runway multiplied by 1.15.

AUTOMATIC LANDING

The RLD for an automatic landing is the greater of:

- The ALD calculated in the automatic landing multiplied by 1.15
- The RLD in the manual mode.

CAUTION	LDG PERF does not automatically check that the RLD for automatic landing is higher than or equal to the RLD in manual mode.

DISPATCH REQUIREMENTS

Applicable to: ALL

REQUIREMENT ON THE LANDING DISTANCE

The Landing Distance Available (LDA) at destination must be at least equal to the Required Landing Distance (RLD) for the planned landing weight.
In the case of a dispatch with a MEL or CDL item, the LDA must be at least equal to the RLD calculated with the applicable MEL or CDL item selected.
In all cases, the dispatch requirement is: RLD ≤ LDA.

REQUIREMENT ON THE GO-AROUND PERFORMANCE

In Normal, CAT II, and CAT III conditions, the go-around climb gradient must be at least equal to:
- 2.7 %
- The gradient published in the airport approach chart.

DIVERSION REQUIREMENTS

Applicable to: ALL

In the case of a diversion, the flight crew calculates the landing distance based on the ALD plus Operator's margins, and the go-around climb gradient in the forecasted conditions at the diversion airport. The LDA at the diversion airport must be at least equal to this landing distance. The requirement for the go-around climb gradient for the diversion is defined in the same way as in the dispatch requirement.

IN-FLIGHT FAILURE REQUIREMENTS

Applicable to: ALL

In the case of a failure that occurs during the flight and that affects the landing performance, the resulting landing distance with failure is the ALD with failure plus Operator's margins.
The ALD with failure is equal to the ALD without failure multiplied by the landing distance coefficient associated to the failure.
For more information about the landing performance following failure, *Refer to Landing Performance Following Failure - General* .

OVERWEIGHT LANDING REQUIREMENTS

Applicable to: ALL

In exceptional conditions, for example an in-flight turn-back, or a diversion, the flight crew can land the aircraft at a weight above the certified Maximum Landing Weight (MLW).
In the case of an overweight landing, the flight crew calculates the landing distance based on the ALD plus Operator's margins, and the go-around climb gradient. The LDA must be at least equal to this landing distance. The requirement for the go-around climb gradient for the overweight landing is the same as in the dispatch requirement. For more information about the dispatch requirement, *Refer to PER-LND-GEN Dispatch Requirements* .

L2 As per Overweight Landing Procedure, if a go-around in CONF 3 (landing in CONF FULL) does not comply with the go-around gradient constraint, the flight crew lands in CONF 3 and performs go-around in CONF 1+F.

L3 The go-around in CONF 1+F is permitted because VS1G of the go-around configuration (CONF 1+F) is less than VS1G of the landing configuration (CONF 3) multiplied by 1.1.

L1 The flight crew must apply the abnormal procedure for overweight landing. For more information about the Overweight Landing Procedure, *Refer to PRO-ABN-ECAM-10-80-50 MISC OVERWEIGHT LDG* .

L2 In the case of an overweight landing, LDG PERF uses the recommended application sequence of braking means for the computation. LDG PERF considers that the flight crew applies maximum braking after the nosewheel touchdown.

USE OF THE AUTOBRAKE SYSTEM

Applicable to: ALL

The autobrake system helps the flight crew in the case of:
- Rejected takeoffs
- Landing.

L2 For more information about the autobrake system, *Refer to DSC-32-10-30-20 Autobrake* .

SEVERE ICING

Applicable to: ALL

The OIS does not take into account severe icing conditions.

Therefore, the flight crew must manually decrease the approach climb limiting weight by 7 % if:
- Icing conditions are predicted during the flight
- The Total Air Temperature (TAT) is less than 10 °C
- There is a significant ice accretion on the non-heated structure.

Intentionally left blank

LDG PERF INITIALIZATION

Applicable to: ALL

FLT OPS STS

The Flight Operations Status (FLT OPS STS) page defines the aircraft context (aircraft registration, MSN) and the flight context (flight number, city pair).

The purpose of the aircraft and flight contexts is to:
- Secure the communication between the FLT OPS applications
- Prevent the use of incorrect inputs coming from another flight.

This common reference page enables the other FLT OPS applications to synchronize with the aircraft and flight data entered in the FLT OPS STS page.
For more information about the FLT OPS STS page, *Refer to DSC-46-20-10-30 FLT OPS STS Page* .

PREREQUISITE TO START LDG PERF

FLIGHT OPERATION STATUS

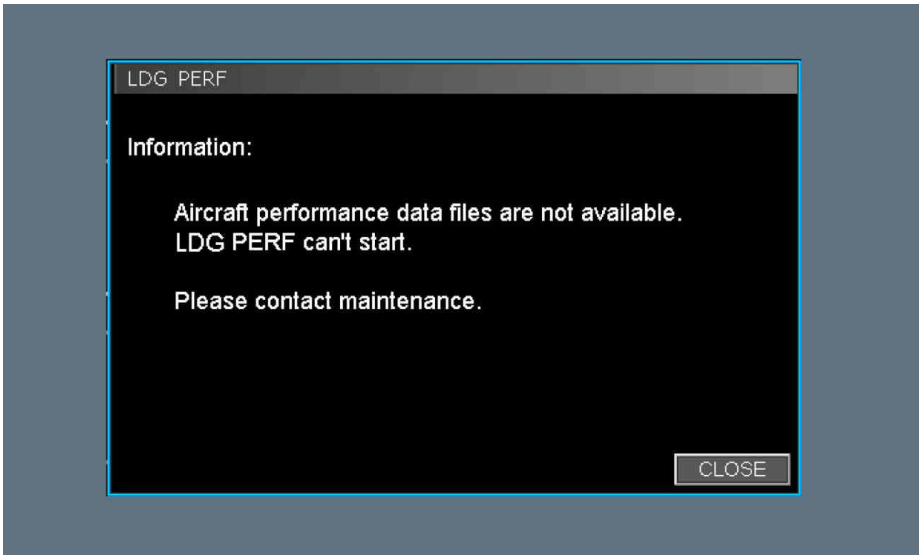
To enable the start of LDG PERF, the following mandatory parameters must be defined in the FLT OPS STS page:
- The aircraft registration (ACFT REGISTRATION)
- The manufacturer serial number (MSN)
- The flight number (FLT NBR)
- The departure airport (FROM)
- The destination airport (TO).

If one of the previous parameters is not defined, the flight crew cannot start LDG PERF.
When the flight crew starts LDG PERF, the destination airport (TO) of the FLT OPS STS page is automatically transferred in LDG PERF and displayed in yellow in the AIRPORT field of the SINGLE RWY COMPUTATION panel.

PERFORMANCE DATABASES

When the flight crew starts LDG PERF without the relevant performance databases, the following error message appears and LDG PERF cannot start:

Error at LDG PERF Start



The flight crew needs to contact the ground.

CHANGE OF AIRPORT IN LDG PERF

Applicable to: ALL

When the flight crew changes the destination airport directly in LDG PERF, this is considered as a landing performance calculation during a diversion.
The flight remains the same so the FLT OPS STS page parameters do not change.

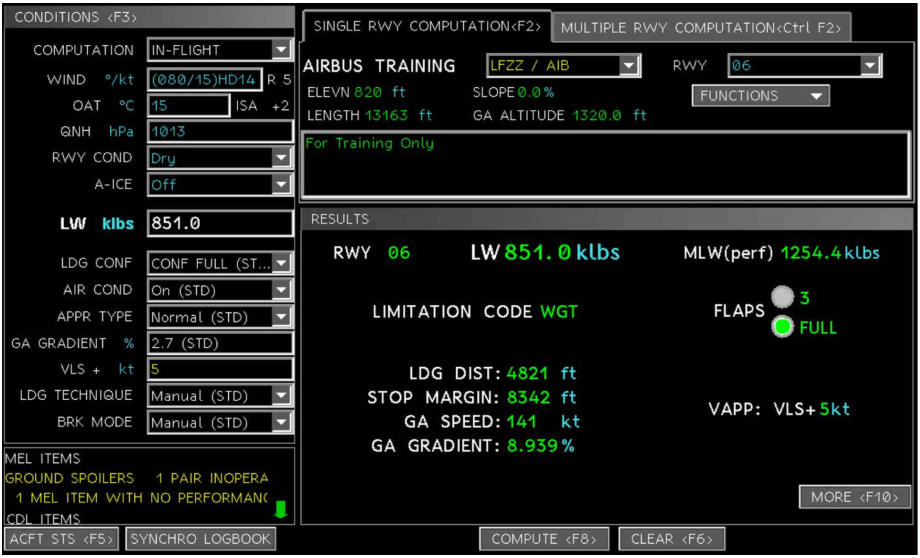
To avoid the use of irrelevant landing data corresponding to the FLT OPS STS airport, the application:

- Resets to default values all input data of LDG PERF
- Defaults the LW to the MSLW
- Deletes previous LDG PERF results
- Keeps MEL, CDL, and ECAM ALERTS selected and valid
- Breaks the connection to LOADSHEET (communication capability with LOADSHEET is lost).

LDG PERF INTERFACE

Applicable to: ALL

LDG PERF Interface



SINGLE RWY COMPUTATION / MULTIPLE RWY COMPUTATION

The flight crew can:
- Select one or more runway(s)
- View the runway characteristics
- Modify the selected runway(s).

For more information about airports and runways:
- *Refer to Dispatch Mode* , or
- *Refer to In Flight Mode* .

CONDITIONS

This panel displays the outside conditions and the desired aircraft configuration:

OUTSIDE CONDITIONS

The flight crew enters the outside conditions.

For more information about the outside conditions:
- *Refer to Dispatch Mode* , or
- *Refer to In Flight Mode* .

AIRCRAFT CONFIGURATION

The flight crew selects the desired aircraft configuration.

For more information about the aircraft configuration:
- *Refer to Dispatch Mode* , or
- *Refer to In Flight Mode* .

AIRCRAFT STATUS

The flight crew can select:
- Inoperative systems that affect the landing performance
- CDL items that affect the landing performance
- ECAM alerts that affect the landing performance.

For more information about the aircraft status:
- *Refer to Dispatch Mode* , or
- *Refer to In Flight Mode* .

RESULTS

The layout of the RESULTS panel depends on the computation mode.

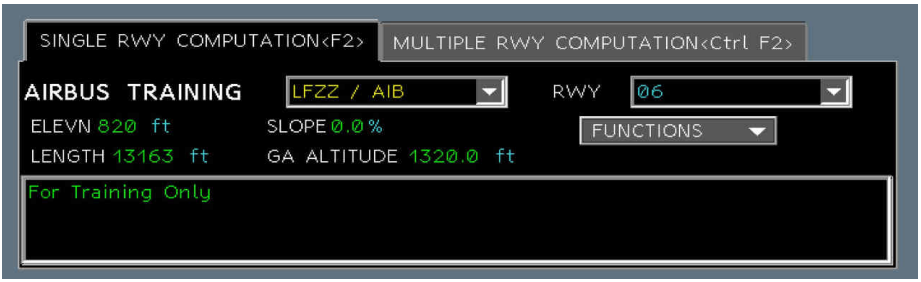
For more information about the landing calculation results:
- *Refer to Dispatch Mode — Single Runway* , or
- *Refer to Dispatch Mode — Multiple Runway* , or
- *Refer to In Flight Mode — Single Runway* , or
- *Refer to In Flight Mode — Multiple Runway* , or
- *Refer to Landing Performance Following Failure* .

AIRPORT PANEL

Applicable to: ALL

The flight crew uses the airport panel to select the airport and runway(s).

Airport Panel



SINGLE RWY COMPUTATION

For more information about the SINGLE RWY COMPUTATION panel, *Refer to PER-LND-LCD-RWY SINGLE RWY COMPUTATION Panel* .

MULTIPLE RWY COMPUTATION

For more information about the MULTIPLE RWY COMPUTATION panel, *Refer to PER-LND-LCD-RWY MULTIPLE RWY COMPUTATION Panel* .

FUNCTIONS

For more information about the runway modification FUNCTIONS:

- *Refer to MODIFY RWY - Reduced Mode* , or
- *Refer to FUNCTIONS - Full Mode* .

SINGLE RWY COMPUTATION PANEL

Applicable to: ALL

GENERAL

A landing performance calculation takes into account the following runway characteristics:

- Landing Distance Available (LDA)

L2 For more information about LDA , *Refer to PER-LND-LCD-RWY LDA* .

L1 - Elevation

L2 For more information about elevation, *Refer to PER-LND-LCD-RWY Elevation* .

L1 - Slope

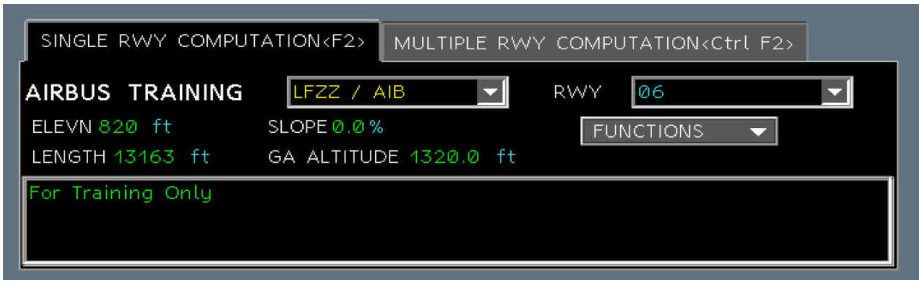
L2 For more information about slope, *Refer to PER-LND-LCD-RWY Slope* .

L1 - Go-around altitude.

L2 For more information about go-around altitude, *Refer to PER-LND-LCD-RWY Go-Around Altitude* .

L1 **LDG PERF**

SINGLE RWY COMPUTATION Panel



The flight crew uses the SINGLE RWY COMPUTATION panel to select the intended runway.

AIRPORT SELECTION

The AIRPORT drop-down list provides a list of available airports. This list is sorted by airport codes.

RUNWAY SELECTION

When the flight crew has selected an airport, the RWY drop-down list provides a choice of runways applicable to that airport.

RUNWAY CHARACTERISTICS

The runway characteristics are:

- Runway ID

- Elevation
- Slope
- Length.

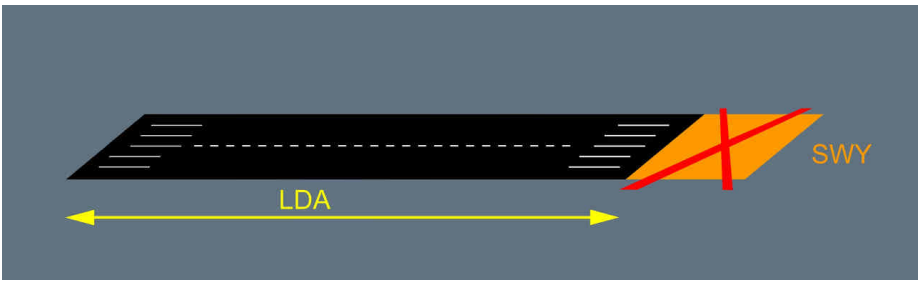
LDA

Applicable to: ALL

The Landing Distance Available (LDA) is the runway length available for landing.

Note: *As per regulation, the stopway is not used for landing calculation.*

Landing Distance and Stopway



ELEVATION

Applicable to: ALL

Runway elevation is the geometric altitude of the runway above mean sea level.

L2 The runway elevation and the QNH are used for pressure altitude determination.

L1 For more information about the effect of pressure altitude on landing performance, *Refer to PER-LND-LCD-OCD QNH* .

SLOPE

Applicable to: ALL

The landing is authorized on runways that have an average slope between -2 % and 2 % .

L2 The upward slope decreases the landing distance.

The downward slope increases the landing distance.

L1 *Note: As per regulation, LDG PERF considers the slope effect only for autoland. For manual landing, the regulatory margin included in the required landing distance covers the slope effect.*

L2 For more information about the Required and the Actual Landing Distance, *Refer to PER-LND-GEN Landing Distance Definitions* .

GO-AROUND ALTITUDE

Applicable to: ALL

The GA ALTITUDE field is optional. The display of GA ALTITUDE is at the Airline's discretion.
GA ALTITUDE is a geometrical altitude. The GA ALTITUDE is specific to the selected airport.

GA ALTITUDE is equal to the sum of:
- A go-around height, which is at the Airline's discretion
- The elevation of the runway threshold.

If GA ALTITUDE does not appear on the Airport panel, LDG PERF computes the go-around gradients at an altitude equal to the runway threshold altitude.
If GA ALTITUDE appears on the Airport panel, LDG PERF computes the go-around gradients at an altitude equal to GA ALTITUDE.
The GA ALTITUDE option enables the flight crew to compute go-around gradients at a more operational go-around height.
The higher the GA ALTITUDE, the lower the go-around gradients.

MODIFY RWY SUBPANEL

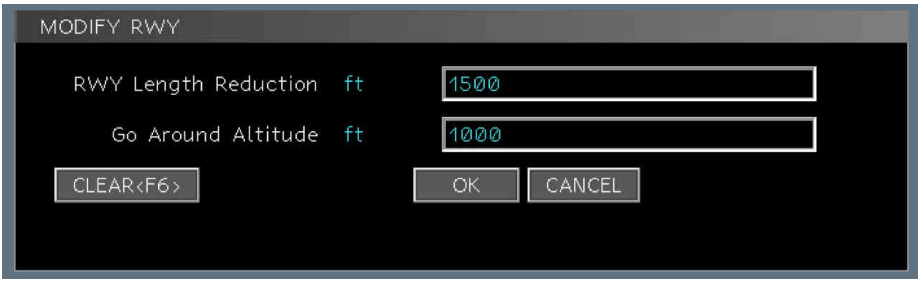
Applicable to: ALL

The flight crew uses the MODIFY RWY subpanel to modify the characteristics of the selected runway by decreasing the runway length or entering the new go-around altitude.

L2 The flight crew can access this subpanel using the MODIFY RWY button of the SINGLE RWY COMPUTATION panel.

For more information about the SINGLE RWY COMPUTATION panel, *Refer to PER-LND-LCD-RWY Airport Panel* .

MODIFY RWY Subpanel



L1 RWY LENGTH REDUCTION

The flight crew can enter the runway length reduction.

The runway length (LENGTH) displayed on the SINGLE RWY COMPUTATION panel is reduced according to the entered value.

The SINGLE RWY COMPUTATION panel displays the label “LENGTH MODIFIED” to indicate that the flight crew has modified the runway length.

GO-AROUND ALTITUDE

The "Go Around Altitude" field is optional and is displayed if this information is available on the SINGLE RWY COMPUTATION panel.

The flight crew can enter a new go-around altitude value.

The go-around altitude (GA ALTITUDE) displayed on the SINGLE RWY COMPUTATION panel is equal to the value entered in the MODIFY RWY Subpanel.

The SINGLE RWY COMPUTATION panel displays the label “GA ALTITUDE MODIFIED” to indicate that the flight crew has modified the go-around altitude.

L2 For more information about the go-around altitude, *Refer to PER-LND-LCD-RWY Go-Around Altitude* .

CREATE RWY - FULL MODE

Applicable to: ALL

FUNCTIONS

The FUNCTIONS drop down list enables the flight crew to:

- MODIFY RWY: To modify the characteristics of an existing runway
- RESTORE RWY: To reset to default values the characteristics of an existing runway after the flight crew has modified it
- CREATE RWY: To create a new runway for an existing airport or for a new airport
- EDIT RWY: To edit the characteristics of the runway that the flight crew has created
- DELETE RWY: To delete a previously created runway.

MODIFY RWY

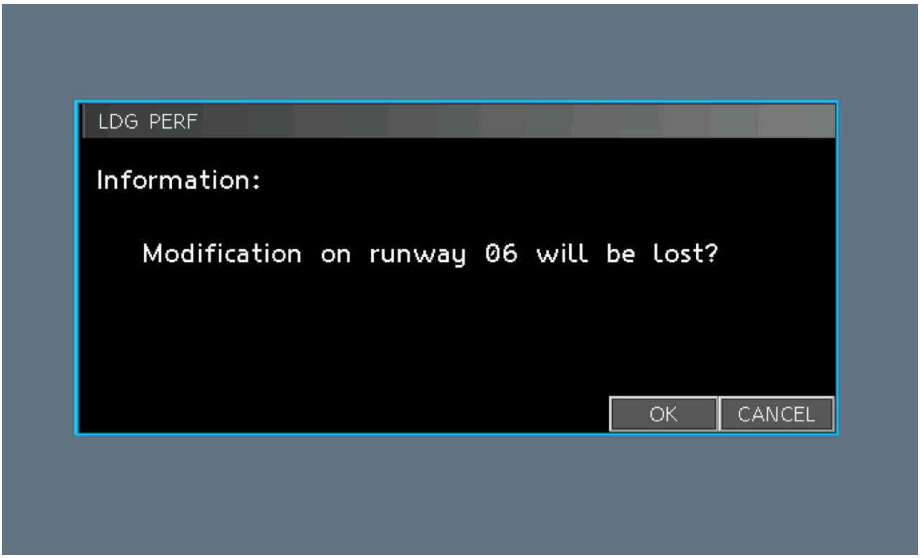
The flight crew uses the RUNWAY MODIFICATION/CREATION Panel to modify the characteristics of the selected runway.

L2 The flight crew can access this panel by selecting MODIFY RWY in the FUNCTIONS drop down list of the SINGLE RWY COMPUTATION panel.

RUNWAY MODIFICATION/CREATION Panel

L1 The runway characteristics displayed on the SINGLE RWY COMPUTATION panel are updated according to the entered value.
The SINGLE RWY COMPUTATION panel displays the label “MODIFIED” after the runway ID to indicate that the flight crew has modified the characteristics of the runway. Each modified runway characteristic is displayed with the color cyan.
If a runway has already been created or modified for an airport, and if the flight crew selects MODIFY RWY for another runway of the same airport, a dialog box warns the flight crew that the previous created or modified runway will be lost.

Dialog Box



RESTORE RWY

The flight crew can reset to default values the characteristics of an existing runway after it has been modified.

CREATE RWY

The RUNWAY MODIFICATION/CREATION panel enables the flight crew to:
- Create a new runway for an existing airport, or
- Create a new airport with an associated runway.

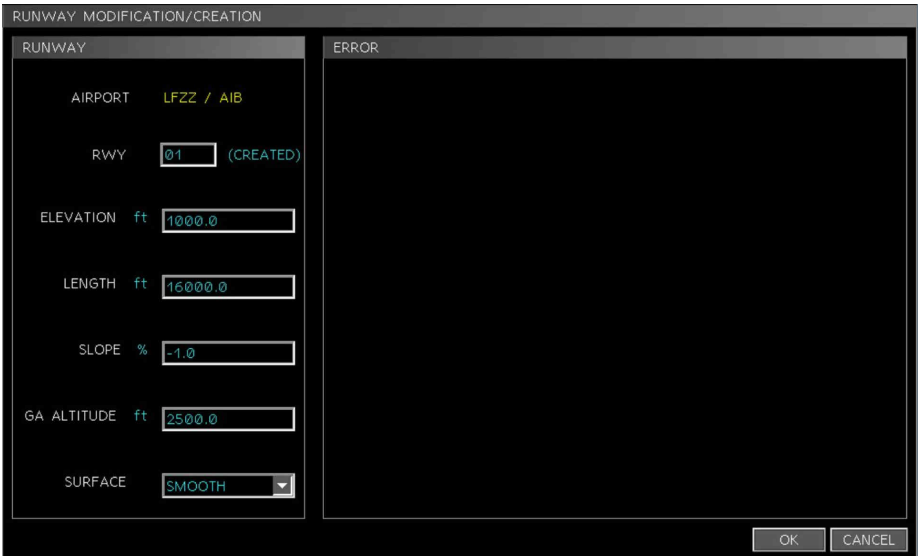
The SINGLE RWY COMPUTATION panel displays the label “CREATED” after the runway ID to indicate that the flight crew has created a new runway.

CREATE A NEW RUNWAY FOR AN EXISTING AIRPORT

To create a new runway for an existing airport, the flight crew:
- First selects an existing airport in the AIRPORT drop down list of the SINGLE RWY COMPUTATION panel, and
- Then selects CREATE RWY in the FUNCTIONS drop down list of the SINGLE RWY COMPUTATION panel.

LDG PERF displays the following panel:

RUNWAY MODIFICATION/CREATION Panel



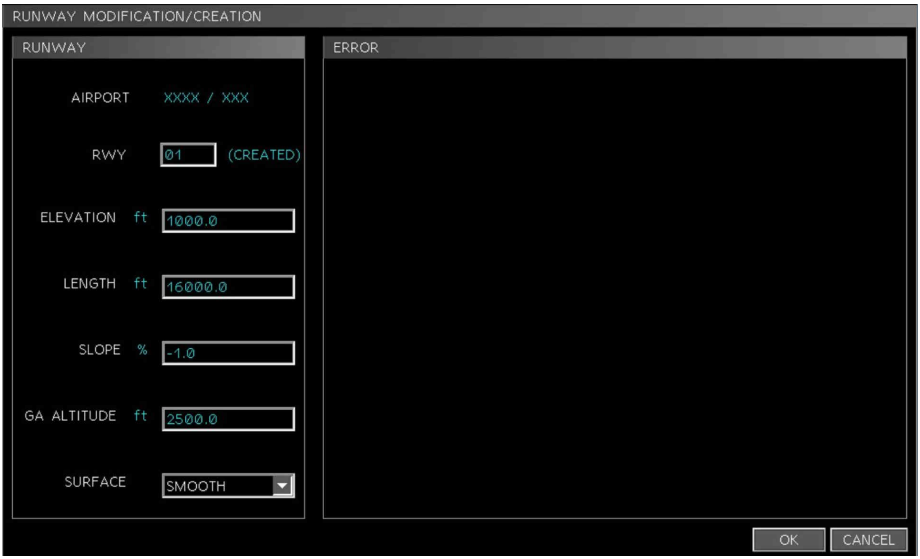
Note: The field SURFACE appears on the RUNWAY MODIFICATION/CREATION panel. This option should not be available as the A380 has not the grooved runway option capability. The selection of the GROOVED/PFC option does not lead to additional landing benefit. Whatever the SURFACE selection, the LDG PERF calculation considers the SMOOTH SURFACE.

CREATE A NEW AIRPORT WITH AN ASSOCIATED RUNWAY

To create a new airport with an associated runway, the flight crew:
- First checks that the AIRPORT drop down list of the SINGLE RWY COMPUTATION panel is empty, and
- Then selects CREATE RWY in the FUNCTIONS drop down list of the SINGLE RWY COMPUTATION panel.

LDG PERF displays the following panel:

RUNWAY MODIFICATION/CREATION Panel



Note: The field SURFACE appears on the RUNWAY MODIFICATION/CREATION panel. This option should not be available as the A380 has not the grooved runway option capability. The selection of the GROOVED/PFC option does not lead to additional landing benefit. Whatever the SURFACE selection, the LDG PERF calculation considers the SMOOTH SURFACE.

EDIT RWY

When the flight crew has created a new runway, he can then edit the characteristics of this runway.

DELETE RWY

The flight crew can only delete a runway that has been previously created. The flight crew cannot delete the runways already available in the airport database loaded into LDG PERF.
To delete a runway, the flight crew selects DELETE RWY in the FUNCTIONS drop down list of the SINGLE RWY COMPUTATION panel.

MULTIPLE RWY COMPUTATION PANEL

Applicable to: ALL

The flight crew uses the MULTIPLE RWY COMPUTATION panel to select several runways for which computation will be performed in the current conditions.
L2 This function increases calculation time.

MULTIPLE RWY COMPUTATION Panel

L1 AIRPORT SELECTION

The AIRPORT drop-down list provides a list of the available airports.

RUNWAY TABLE

The flight crew uses the runway table to select the runways on which the computation will be performed.

Intentionally left blank

OUTSIDE CONDITIONS SUBANEL

Applicable to: ALL

The Outside Conditions subpanel provides the following information:

- Wind
- Outside Air Temperature (OAT)
- Pressure at the Mean Sea Level (QNH)
- Runway conditions
- Anti-ice status.

Outside Conditions Subpanel

WIND

Applicable to: ALL

GENERAL

L2 The longitudinal wind component affects the aircraft ground speed, and therefore the landing distances.

L1 The landing distance decreases in the case of headwind, and increases in the case of tailwind.

L2 In the case of headwind, the Approach Speed (VAPP) must additionally be increased to avoid speed loss close to the ground, since wind speed is often reducing as the aircraft descends. As a result, the beneficial headwind effect on the landing distance is compensated for by the increase of the Approach Speed (VAPP).
As per regulation, the computation is based on 150 % of the entered tailwind, and 50 % of the entered headwind.

L1 The crosswind component does not affect the calculation of the landing distance. However, a maximum crosswind component is demonstrated.
For more information about crosswind limitation, *Refer to PER-LND-CTA-CWD Crosswind* .

LDG PERF

There are two ways to define wind values:
- Longitudinal Speed Component
- Direction/Speed (or Direction/Speed/Gust) Combination.

The Direction/Speed (or Direction/Speed/Gust) Combination is required in the case of a MULTIPLE RUNWAY COMPUTATION.

Note: *Displayed wind values are rounded mathematically instead of conservatively, but there is no impact on the computation, which uses exact values.*

LONGITUDINAL SPEED COMPONENT

The flight crew enters the longitudinal component with:
- H or HD followed by the headwind speed (e.g. H10 or HD5), or
- T or TL followed by the tailwind speed (e.g. T6 or TL8).

Wind Values Input - Longitudinal Speed Component

DIRECTION/SPEED (OR DIRECTION/SPEED/GUST) COMBINATION

This wind input mode is compulsory when computations are made on multiple runways.

The flight crew can enter:
- The wind direction and the wind speed, or
- The wind direction, the wind speed, and the gust, if this option is enabled.

Direction/Speed Combination

The speed entry is projected along the runway axis and perpendicular to the runway axis. The longitudinal projection follows the same display rules as the longitudinal speed component entry mode.

LDG PERF displays the crosswind as:
- R, if the wind comes from the right, or
- L, if the wind comes from the left.

Wind Values Input - Direction/Speed Combination

Direction/Speed/Gust Combination

This entry mode is possible if a maximum crosswind limit is defined as gust included for one RWY COND at least.

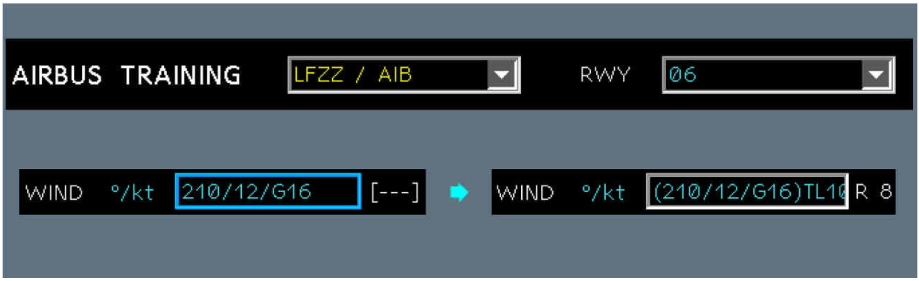
In this case, the flight crew can enter the value of the gust with the prefix G followed by the gust value (e.g. G16).
The speed entry (gust respectively) is projected along the runway axis and perpendicular to the runway axis.
The longitudinal projection follows the same display rules as the longitudinal speed component entry mode.

LDG PERF displays the crosswind as:
- R, if the wind comes from the right, or
- L, if the wind comes from the left.

If the flight crew enters the gust, LDG PERF displays the perpendicular projection of the gust as the crosswind.

LDG PERF uses:
- The gust perpendicular component for the check of the maximum crosswind limitation if this one is defined as gust included for the selected RWY COND
- The steady wind perpendicular component for the check of the maximum crosswind limitation if this one is not defined as gust included for the selected RWY COND.

Wind Values Input - Direction/Speed/Gust Combination



OUTSIDE AIR TEMPERATURE

Applicable to: ALL

GENERAL

The Outside Air Temperature (OAT) affects the go-around performance.

Note: As per regulation, the effect of temperature on landing distance is only taken into account for water contaminated runway or autoland.

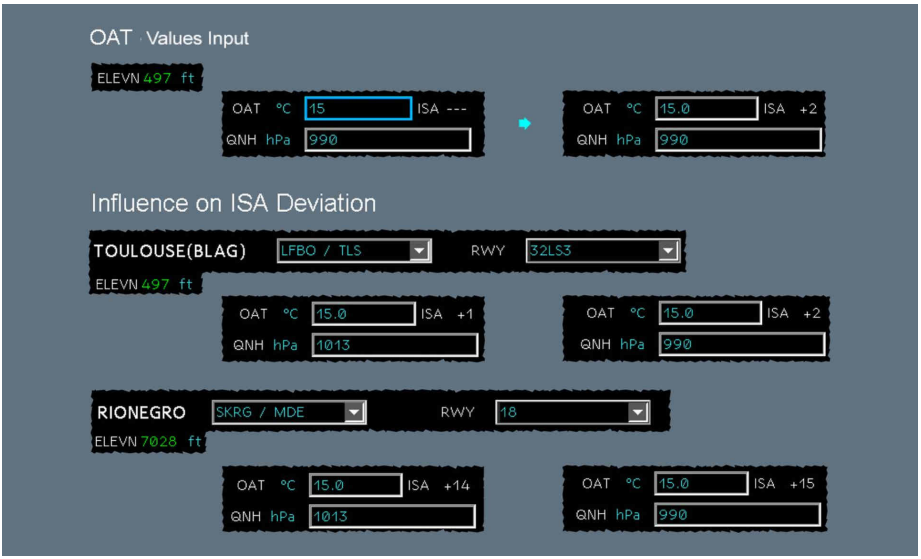
TEMPERATURE EFFECT ON ENGINE THRUST

The thrust provided by the engines at go-around rating (TOGA) versus OAT is constant up to the flat rating temperature (TREF).

When the OAT increases,
- The available engine thrust decreases above TREF
- The go-around climb gradients decrease.

LDG PERF

OAT Input



OAT VALUE INPUT

The OAT is the input parameter that gives the temperature at the arrival airport.

L2 The range of permitted OAT is the certified environmental envelope for landing, which depends on the airport pressure altitude and the runway condition.

L1 The deviation from the International Standard Atmosphere (ISA) is automatically computed and displayed next to the OAT field.

INFLUENCES ON ISA DEVIATION

The deviation from ISA is influenced by:

- The airport elevation
- The QNH value.

L2 For more information about the QNH , *Refer to PER-LND-LCD-OCD QNH* .

QNH

Applicable to: ALL

GENERAL

The QNH is the pressure at the Mean Sea Level (MSL).

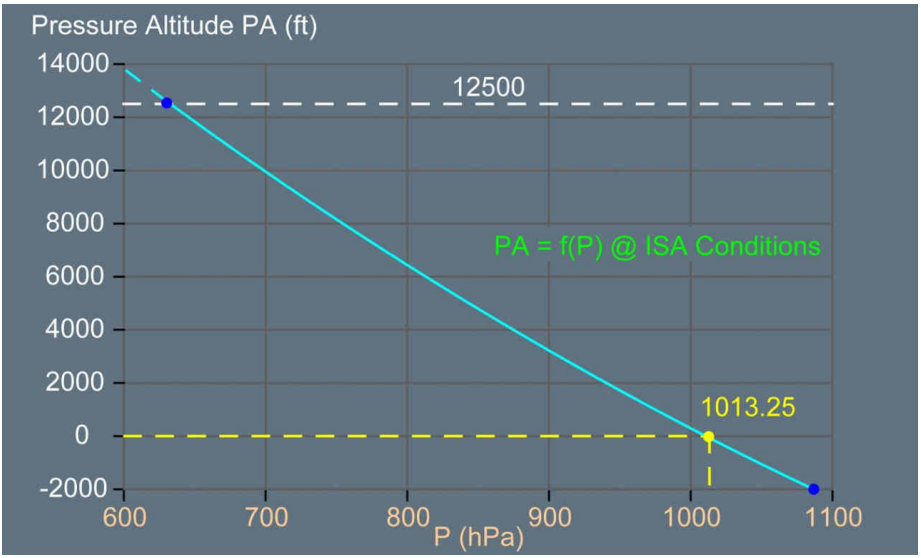
L2 The QNH is calculated from:
- The airport atmospheric pressure
- The airport elevation
  The airport elevation is the geometric altitude of the airport.
- The standard pressure law from ISA atmosphere.

At the airport level, with the QNH setting, in ISA conditions, the altimeter indicates the airport elevation.

L1 The airport Pressure Altitude (PA) depends on the QNH and the airport elevation.

L2 The PA is a barometric measurement converted into an altitude via the ISA law.

PA Function of Pressure (P)



L1 The QNH affects the aircraft landing speed and engine thrust.

QNH EFFECT ON LANDING SPEED

When the QNH decreases at a given airport elevation:
- The PA increases
- The air density ρ decreases
- A higher TAS is required for approach in order to maintain the same lift
- The landing distance is longer.

QNH EFFECT ON ENGINE THRUST

When the QNH decreases at a given airport elevation:
- The PA increases
- The available engine thrust decreases
- The landing distance increases
- The go-around climb gradients decrease.

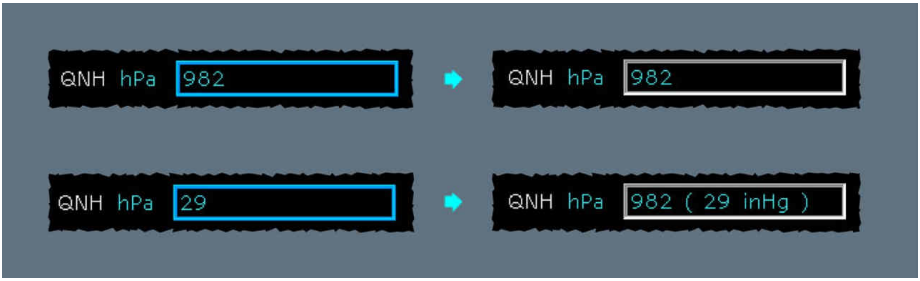
LDG PERF

The QNH is the input parameter that determines the pressure altitude, taking into account the airport elevation.

The flight crew can enter a QNH using the following units:
- Hecto Pascal (hPa)
- Inch of Mercury (inHg).

LDG PERF automatically detects the QNH format. For example, when the flight crew enters 29 for the QNH, LDG PERF automatically converts the value into the appropriate one for hPa unit.

QNH Input



L2 The airport elevation and the go-around altitude affect the QNH range.

RUNWAY CONDITIONS

Applicable to: ALL

GENERAL

The runway surface condition affects the landing performance and must be taken into account for MLW(PERF) calculation.
For more information about the runway conditions, *Refer to Runway Contamination* .

LDG PERF

The flight crew selects one of the following settings from the RWY COND drop-down list depending on the runway surface condition.

DRY

The flight crew selects “Dry” for dry runways.

WET

The flight crew selects “Wet” for runways covered with:
- Less than 0.12 in of Water, or
- Equivalent contaminants in terms of performance:
  - Less than 0.12 in of Slush, or
  - Less than 0.16 in of Wet Snow, or
  - Less than 0.59 in of Dry Snow.

For more information about equivalences, *Refer to PER-LND-CTA Equivalences for Performance* .

WATER 1/4" (6.3 MM)

The flight crew selects ”Water 1/4” (6.3 mm)” between 0.12 in and 0.50 in of Standing Water.
L2 For landing performance assessment, a higher contaminant depth systematically produces shorter landing distances. Airports tend to overestimate contaminant thicknesses in their reporting. This may result in a calculated landing distance shorter than the achievable one. As a consequence, Airbus does not recommend the operational use of the landing distance information corresponding to the "Water 1/2" (12.7 mm)" and "Slush 1/2" (12.7 mm)".

L1 SLUSH 1/4" (6.3 MM)

The flight crew selects “Slush 1/4" (6.3 mm)” for runways covered with:
- Between 0.12 in and 0.50 in of Slush, or
- Equivalent contaminants in terms of performance:
  - Between 0.16 in and 1.00 in of Wet Snow, or

- Between 0.59 in and 4.00 in of Dry Snow.

For more information about equivalences, *Refer to PER-LND-CTA Equivalences for Performance* .

L2 For landing performance assessment, a higher contaminant depth systematically produces shorter landing distances. Airports tend to overestimate contaminant thicknesses in their reporting. This may result in a calculated landing distance shorter than the achievable one. As a consequence, Airbus does not recommend the operational use of the landing distance information corresponding to the "Water 1/2" (12.7 mm)" and "Slush 1/2" (12.7 mm)".

L1 **COMPACTED SNOW**

The flight crew selects “Compacted snow” for runways covered with Compacted Snow.

ICY

The flight crew selects "Icy" for runways covered with ice.

CAUTION	Landing on icy runway is not recommended.

ANTI-ICE

Applicable to: ALL

GENERAL

The engine bleed air system supplies high-pressure air to the following systems:
- Air conditioning and cabin pressurization
- Wing anti-ice and engine anti-ice
- Engine start
- Hydraulic reservoir pressurization
- Pack bay ventilation system.

L2 For more information about the engine bleed air system, *Refer to DSC-36-10-20-10 Engine Bleed Air System* .

L1 The air conditioning and the anti-ice (wing, engine) systems affect the landing performance. The engine bleeds reduce the available engine power. As a result, the go-around gradient decreases. The FADEC compensates to a large extent the thrust loss due to “Engine only” anti-ice.

LDG PERF

The flight crew selects one of the following setting from the A-ICE drop-down list:
- Off
- Engine only
- Engine & Wing.

AIRCRAFT CONFIGURATION SUBPANEL

Applicable to: ALL

The Aircraft Configuration subpanel provides the following information:

- Landing weight (LW)
- Aerodynamic configuration
- Airflow
- Approach type
- Go-around gradient
- Approach speed
- Landing technique.

Aircraft Configuration Subpanel

LANDING WEIGHT

Applicable to: ALL
Impacted by TDU: 00021446 Landing Weight

GENERAL

The estimated Landing Weight (LW) at dispatch must not exceed:
- The certified Maximum Landing Weight (MLW)
- The Maximum Landing Weight Limited by the Performance (MLW(PERF)).

L2 For more information about MLW(PERF) , *Refer to PER-LND-LRD-DSR Landing Weights* .

L1 LDG PERF

The flight crew enters the planned LW value.
The flight crew can use the shortcut "*" to insert the MLW .
The LW entered must be less than the certified MLW , defined as per operator policy.
LDG PERF permits the overweight landing computation only for the In-Flight computation type.

COMMUNICATION FROM LOADSHEET TO LDG PERF

When the flight crew completes a LOADSHEET computation and then changes from LOADSHEET to LDG PERF, LOADSHEET transfers the calculated LW value to LDG PERF. LDG PERF displays this value in yellow in the CONDITIONS panel.

LANDING WEIGHT

Applicable to: ALL
Impacted DU: 00011596 Landing Weight

GENERAL

The estimated Landing Weight (LW) at dispatch must not exceed:
- The certified Maximum Landing Weight (MLW)
- The Maximum Landing Weight Limited by the Performance (MLW(PERF)).

L2 For more information about MLW(PERF) , *Refer to PER-LND-LRD-DSR Landing Weights* .

L1 LDG PERF

The flight crew enters the planned LW value.
The flight crew can use the shortcut "*" to insert the MLW .
The LW entered must be less than the certified MLW , defined as per operator policy.
LDG PERF permits the overweight landing computation only for the In-Flight computation type.

COMMUNICATION FROM LOADSHEET TO LDG PERF

When the flight crew completes a LOADSHEET computation and then changes from LOADSHEET to LDG PERF, LOADSHEET transfers the calculated LW value to LDG PERF. LDG PERF displays this value in yellow in the CONDITIONS panel.

Note: When both LOADSHEET and LDG PERF are opened, LDG PERF always takes the landing weight from the LOADSHEET results.
Check the landing weight in LDG PERF before any calculation, particularly in the case of a diversion.

CG POSITION

Applicable to: ALL

GENERAL

The Center of Gravity (CG) position affects the balance of forces applied on the aircraft. As a result, the CG position affects the aircraft performance, particularly the Approach Speed (VAPP) and the go-around speed.

L2 The CG position has a direct effect on the stalling speeds. A forward CG increases the stalling speeds and an aft CG reduces them. Therefore, the CG position affects the VAPP and the go-around speed and thus the entire landing performance.

L1 LDG PERF

The CG field is expressed in % of the Mean Aerodynamic Chord (MAC).
In accordance with aircraft certification, and without failure in flight, the CG is assumed to be at the most forward limit for all computations. The CG field does not appear on the CONDITIONS panel.
In the case of the selection of a failure in flight, the CG field becomes available on the CONDITIONS panel, in order to reduce conservatism on the approach speed in such a degraded situation. The VAPP computation takes into account the value that the flight crew enters in the CG field, but the landing distance computation considers that the CG is at the most forward limit.

L2 For more information about the CG in the case of a failure in flight, *Refer to Landing Performance Following Failure - Impact on Conditions* .

AERODYNAMIC CONFIGURATION

Applicable to: ALL

GENERAL

The certified landing configurations are:
- CONF 3
- CONF FULL.

CONF FULL is recommended.
The selection of an aerodynamic configuration affects the landing performance.
L2 At a given speed, a higher flap setting increases the lift, but also increases the drag. Therefore, a higher flap setting decreases the landing distance, but also decreases the go-around gradient.

L1 LDG PERF

LDG PERF provides two types of calculation related to the aerodynamic configuration:
- For a given flap setting (CONF 3, CONF FULL)
- AUTO CONF.

When the flight crew selects AUTO CONF, LDG PERF computes the landing performance for:
- Landing in CONF FULL (go-around in CONF 3)
- Landing in CONF 3 (go-around in CONF 2).

If both a go-around in CONF 3 (landing in CONF FULL) and a go-around in CONF 2 (landing in CONF 3) comply with the go-around gradient constraint, then LDG PERF displays the results for: landing in CONF FULL (go-around in CONF 3).
If a go-around in CONF 3 (landing in CONF FULL) does not comply with the go-around gradient constraint, the flight crew lands in CONF 3 and performs go-around in CONF 2. LDG PERF displays the results for: landing in CONF 3 (go-around in CONF 2).

AIRFLOW

Applicable to: ALL

GENERAL

The engine bleed air system supplies high-pressure air to the following systems:
- Air conditioning and cabin pressurization
- Wing anti-ice and engine anti-ice
- Engine start
- Hydraulic reservoir pressurization
- Pack bay ventilation system.

L2 For more information about the engine bleed air system, *Refer to DSC-36-10-20-10 Engine Bleed Air System* .

L1 The air conditioning and the anti-ice (wing, engine) systems affect the landing performance. The engine bleeds reduce the available engine power. As a result, the go-around gradient decreases.

LDG PERF

The flight crew selects one of the following setting from the AIR COND drop-down list:
- On
- Off.

APPROACH TYPE

Applicable to: ALL

GENERAL

As the A380 is a four-engined aircraft, the approach type does not affect the minimum go-around gradient (2.7 %).

L2 The CAT II minimum go-around gradient (2.5 %) is lower than the CAT I minimum go-around gradient (2.7 %) for a four-engined aircraft.

L1 The approach type affects the go-around speed for the approach climb calculation:

- For CAT I approach type: The go-around speed is equal to VLS (1.23 VS1G) of the approach configuration
- For CAT II approach type: The go-around speed is equal to the maximum of:
  - VLS of the approach configuration (landing gear retracted)
  - VLS of the landing configuration (landing gear extended) + 5 kt
  - Minimum Control Airspeed for Landing (VMCL) + 5 kt.

As a result, the approach type only affects the approach climb gradient calculation.

LDG PERF

The flight crew selects one of the following approach types:

- Normal, for a CAT I approach
- CAT II, for a CAT II or a CAT III approach.

GO-AROUND GRADIENT

Applicable to: ALL

GENERAL

As per regulation the aircraft must achieve the minimum go-around gradient which is the maximum of:

- 2.7 %
- The value published in the go-around procedure.

L2 For more information about the go-around gradient, *Refer to PER-LND-LRD-DSR Go-Around Gradient* .

L1 LDG PERF

The flight crew can use the shortcut "MIN" to insert the minimum regulatory go-around gradient value.

To compute with a go-around gradient more than the minimum one, the flight crew enters the required gradient in GA GRADIENT.

USER SPEED INCREMENT - VLS+

Applicable to: ALL

GENERAL

The Approach Speed (VAPP) is the speed of the aircraft when crossing the runway threshold.

VAPP is the sum of:

- VLS

L2 VLS is the Lowest Selectable Speed
VLS is equal to 1.23 VS1G

L1 - The wind speed increment

L2 The wind correction is equal to 1/3 of the headwind. The wind correction is limited to 15 kt .
When A/THR is selected, a minimum wind correction of 5 kt is required.

L1 - The CDL speed increment
- An extra value selected at the flight crew discretion.

LDG PERF

The default value of the increment on the approach speed field (VLS+) is equal to the wind speed increment, considering that the A/THR is ON.
The flight crew can increase the default value of the increment on the approach speed.

When the flight crew starts a computation, LDG PERF computes the landing performance with an approach speed equal to the sum of:

- VLS
- The user speed increment
- The CDL speed increment, if the flight crew has selected a CDL item that affects the approach speed.

L2 For more information about the CDL items, *Refer to PER-LND-LCD-AFS CDL* .

LANDING TECHNIQUE

Applicable to: ALL

GENERAL

The autoland systems are designed to help the flight crew for landing in low visibility.

L2 On a dry runway the Actual Landing Distance (ALD) in autoland is the addition of two distances: the airborne phase distance and the ground phase distance.

L1 LDG PERF

The flight crew selects one of the following setting in the LDG TECHNIQUE drop-down list:

- Autoland
- Manual.

When Autoland is selected, the flight crew must enter the glide slope angle.

L2 When the flight crew runs a LDG PERF computation with the LDG TECHNIQUE Autoland, LDG PERF automatically checks that the RLD for automatic landing is more than or equal to the RLD in manual mode:

- If the RLD for automatic landing is more than or equal to the RLD in manual mode, LDG PERF displays the results for a RLD calculated using the Autoland landing technique
- If the RLD for automatic landing is less than the RLD in manual mode, LDG PERF displays the results for a RLD calculated using the Manual landing technique.

AIRCRAFT STATUS PANEL

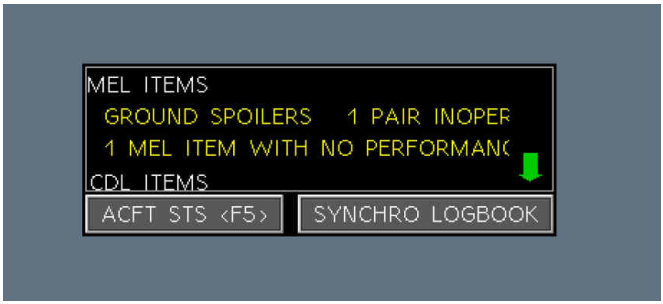
Applicable to: ALL

The current aircraft status must be considered during flight preparation.

The reminder area of the AIRCRAFT STATUS panel lists:
- Inoperative systems impacting landing performance
- The number of MEL items without landing performance impact (if any)
- CDL items impacting landing performance
- The number of negligible CDL items (if any).

If the aircraft is dispatched without any deferred items, "NO PERFORMANCE IMPACT" appears in the reminder area of the AIRCRAFT STATUS panel.

Reminder area of the AIRCRAFT STATUS Panel



SYNCHRO LOGBOOK

The flight crew can recover the eLogbook status by clicking on the "SYNCHRO LOGBOOK" button.
For more information about the SYNCHRO LOGBOOK function, *Refer to PER-LND-LCD-AFS Synchronization with Logbook* .

AIRCRAFT STATUS

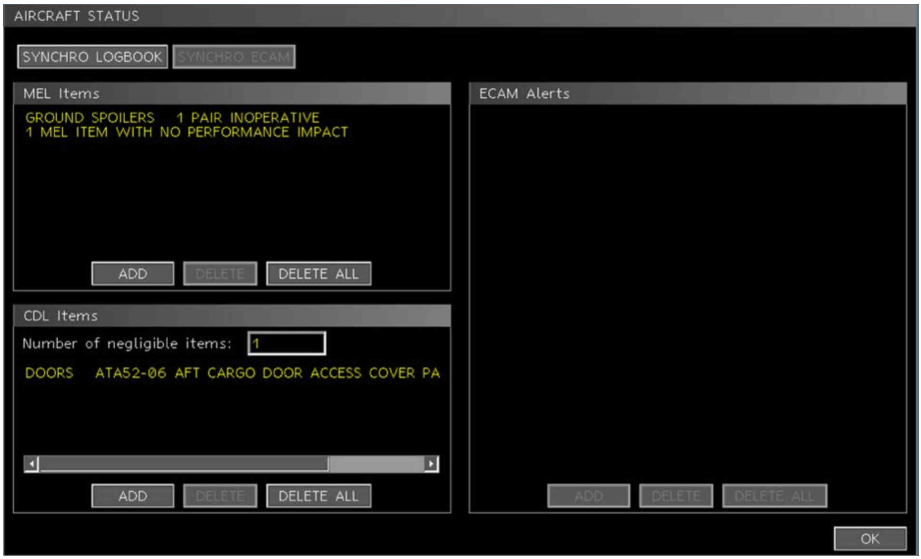
By clicking on the ACFT STS button, the flight crew opens the AIRCRAFT STATUS panel.

The AIRCRAFT STATUS panel is divided in three subpanels:
- MEL items
- CDL items
- ECAM Alerts.
  The ECAM Alerts subpanel is empty and disabled. It does not represent the current status of the ECAM alerts impacting landing performance.

Moreover, the flight crew can recover the eLogbook status by clicking on the "SYNCHRO LOGBOOK" button.

Note: *The ECAM Alerts part is active only for computations in IN-FLIGHT mode.*

AIRCRAFT STATUS Panel



MEL

Applicable to: ALL

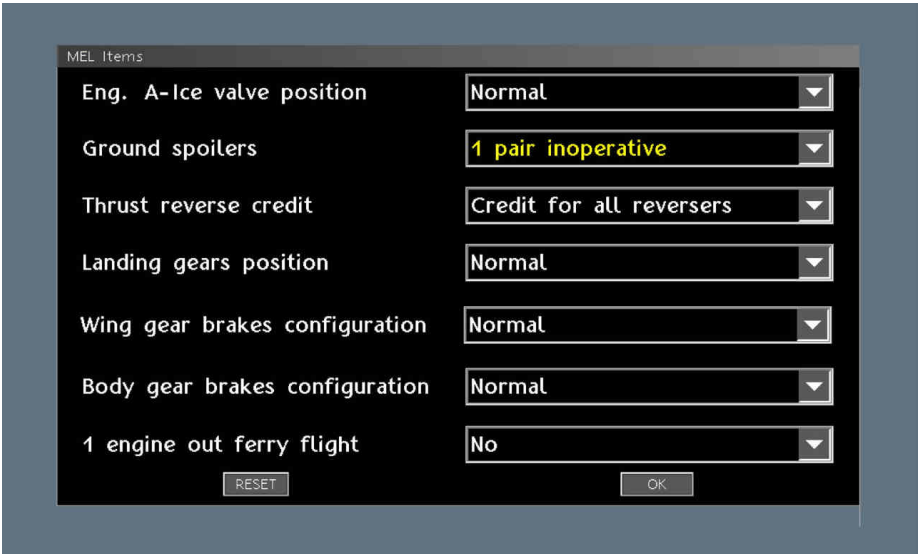
The MEL items subpanel displays the inoperative systems selected by the flight crew using:

- The OPS LIBRARY / MEL manual, via the selection of a MEL item, or
  In this case, the inoperative systems are displayed in yellow on LDG PERF.
- The LDG PERF MEL panel.
  In this case, the inoperative systems are displayed in cyan on LDG PERF.

MEL ITEM SELECTION

To open the MEL items panel, the flight crew uses the ADD button of the MEL items subpanel.
The MEL items panel displays the list of systems that could be inoperative and that involve landing performance penalties.
The flight crew selects inoperative items by selecting the appropriate status for each item in the drop-down lists.
The inoperative system associated to the MEL item is described in the (o) procedure of the MEL item.

MEL Items Panel



The selected item appears in the MEL items subpanel and in the reminder area of the AIRCRAFT STATUS panel.

MEL ITEMS COMBINATION

The flight crew must check that the MEL items combination is permitted for dispatch in the "MEL Items" section of the MEL manual.
T.O PERF does not ensure that the selected combination of inoperative systems is permitted for dispatch.

COMMUNICATION BETWEEN MEL MANUAL AND LDG PERF

When the aircraft is dispatched with MEL items and if these MEL items are selected via the OPS LIBRARY / MEL manual:

- The associated inoperative systems that affect the landing performance are automatically selected and displayed in yellow on the reminder area of the AIRCRAFT STATUS panel in LDG PERF
- The number of MEL items without landing performance impact is displayed in yellow on the reminder area of the AIRCRAFT STATUS panel in LDG PERF.

CDL

Applicable to: ALL

The CDL items subpanel displays the missing structural parts selected by the flight crew using:

- The OPS LIBRARY / CDL manual, via the selection of a CDL item, or
  In this case, the CDL items are displayed in yellow on LDG PERF.
- The LDG PERF CDL panel.
  In this case, the CDL items are displayed in cyan on LDG PERF.

The CDL items subpanel also displays the number of negligible items.

NUMBER OF NEGLIGIBLE ITEMS

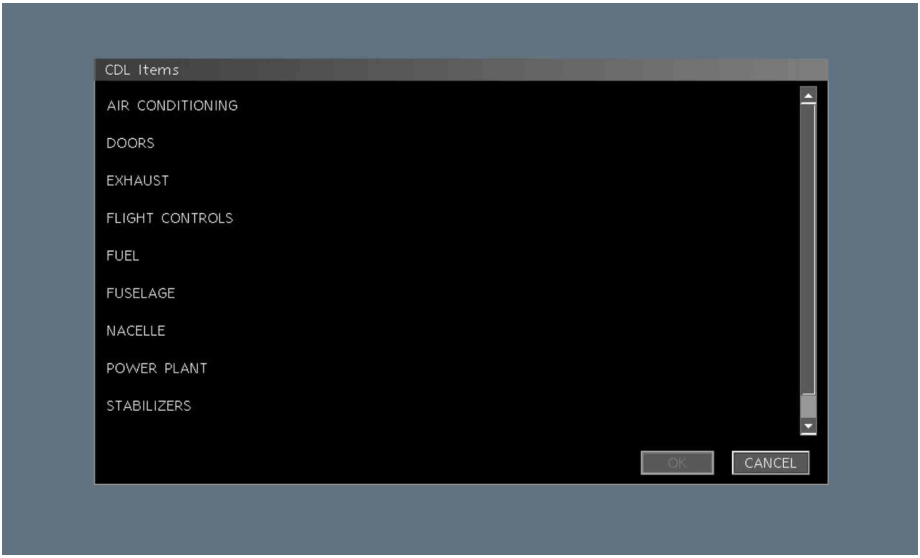
The flight crew enters the number of different structural parts simultaneously missing that have a negligible impact on the performance.

L2 If the number of negligible items is less or equal to three, there is no performance penalty. If the number of negligible items is greater or equal to four, then a drag increase for each item is taken into account for the performance computation.
For more information about the negligible CDL items, *Refer to AFM/MCDL-GEN-PERF Performance penalties published in the Airplane Flight Manual MCDL chapter*.

L1 CDL ITEM SELECTION

To open the CDL items panel, the flight crew uses the ADD button of the CDL items subpanel. The CDL items panel displays the list of structural parts that could be missing and that involve landing performance penalties.

CDL Items Panel



To add a CDL item, the flight crew selects:
- The appropriate system group
- The corresponding CDL item
- The number of items missing

The selected item appears in the CDL items subpanel and in the reminder area of the AIRCRAFT STATUS panel.

Note: *When the flight crew selects a CDL item, the number of missing items is hidden in the ACFT STS box. The flight crew must use the scroll bar to display the hidden information.*

CDL ITEMS COMBINATION

The flight crew must check that the CDL items combination is permitted for dispatch in the Aircraft Flight Manual (AFM).
LDG PERF does not ensure that the selected configuration is permitted for dispatch.

COMMUNICATION BETWEEN CDL MANUAL AND LDG PERF

When the aircraft is dispatched with CDL items and if these CDL items are selected via the OPS LIBRARY / CDL manual:

- The CDL items that affect the landing performance are automatically selected and displayed in yellow on the reminder area of the AIRCRAFT STATUS panel in LDG PERF. Their associated number of missing parts is also displayed.
- The number of CDL items without landing performance impact is displayed in yellow on the reminder area of the AIRCRAFT STATUS panel in LDG PERF. These CDL items are called "negligible items".

When the flight crew uses the OPS LIBRARY / CDL manual to select a specific CDL item that affects the landing performance and then starts LDG PERF, the landing performance module may consider this CDL item as a negligible item if the CDL To LDG PERF communication file does not include this CDL item.
In this case, the flight crew must manually apply the weight reduction described in the OPS LIBRARY / CDL manual to the MLW(PERF) calculated by LDG PERF.

SYNCHRONIZATION WITH LOGBOOK

Applicable to: ALL

The flight crew can use the "SYNCHRO LOGBOOK" button to recover the eLogbook status.
This action synchronizes the aircraft status of the whole FLT OPS domain with the current deferred items of the eLogbook
If the flight crew had previously selected additional MEL and CDL items in LDG PERF (displayed in cyan in the AIRCRAFT STATUS panel) and then uses the SYNCHRO LOGBOOK function, these manually entered items are lost.

Note: *1. When the flight crew uses the SYNCHRO LOGBOOK function in LDG PERF, the whole FLT OPS domain is also synchronized with the eLogbook*
2. If the Logbook status is lost in the FLT OPS domain, LDG PERF may synchronize with an old eLogbook status.

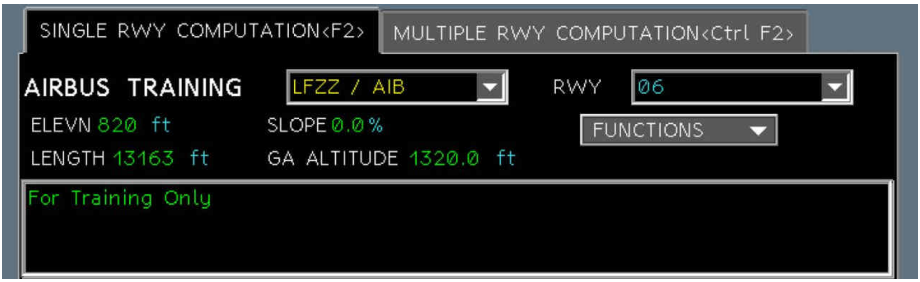
Intentionally left blank

AIRPORT PANEL

Applicable to: ALL

The flight crew uses the airport panel to select the airport and runway(s).

Airport Panel



SINGLE RWY COMPUTATION

For more information about the SINGLE RWY COMPUTATION panel, *Refer to PER-LND-LCF-RWY SINGLE RWY COMPUTATION Panel* .

MULTIPLE RWY COMPUTATION

For more information about the MULTIPLE RWY COMPUTATION panel, *Refer to PER-LND-LCF-RWY MULTIPLE RWY COMPUTATION Panel* .

FUNCTIONS

For more information about the runway modification FUNCTIONS:

- *Refer to MODIFY RWY - Reduced Mode* , or
- *Refer to FUNCTIONS - Full Mode* .

SINGLE RWY COMPUTATION PANEL

Applicable to: ALL

GENERAL

A landing performance calculation takes into account the following runway characteristics:

- Landing Distance Available (LDA)

L2 For more information about LDA , *Refer to PER-LND-LCF-RWY LDA* .

L1 - Elevation

L2 For more information about elevation, *Refer to PER-LND-LCF-RWY Elevation* .

L1 - Slope

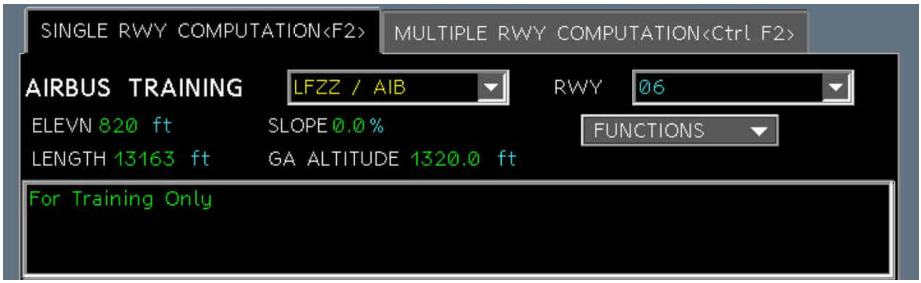
L2 For more information about slope, *Refer to PER-LND-LCF-RWY Slope* .

L1 - Go-around altitude.

L2 For more information about go-around altitude, *Refer to PER-LND-LCF-RWY Go-Around Altitude* .

L1 **LDG PERF**

SINGLE RWY COMPUTATION Panel



The flight crew uses the SINGLE RWY COMPUTATION panel to select the intended runway.

AIRPORT SELECTION

The AIRPORT drop-down list provides a list of available airports. This list is sorted by airport codes.

RUNWAY SELECTION

When the flight crew has selected an airport, the RWY drop-down list provides a choice of runways applicable to that airport.

RUNWAY CHARACTERISTICS

The runway characteristics are:

- Runway ID

- Elevation
- Slope
- Length.

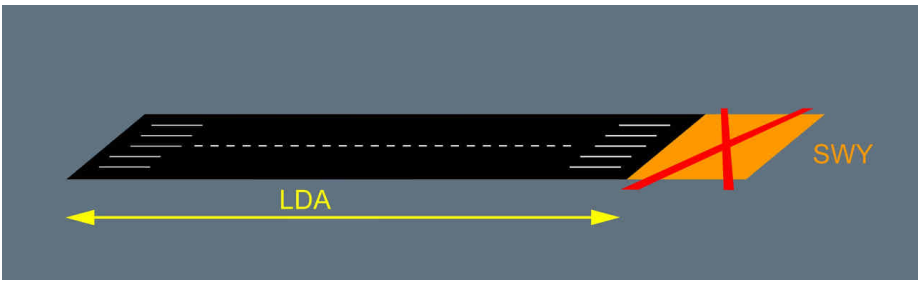
LDA

Applicable to: ALL

The Landing Distance Available (LDA) is the runway length available for landing.

Note: *As per regulation, the stopway is not used for landing calculation.*

Landing Distance and Stopway



ELEVATION

Applicable to: ALL

Runway elevation is the geometric altitude of the runway above mean sea level.

L2 The runway elevation and the QNH are used for pressure altitude determination.

L1 For more information about the effect of pressure altitude on landing performance, *Refer to PER-LND-LCF-OCD QNH* .

SLOPE

Applicable to: ALL

The landing is authorized on runways that have an average slope between -2 % and 2 % .

L2 The upward slope decreases the landing distance.

The downward slope increases the landing distance.

L1 *Note:* *As per regulation, LDG PERF considers the slope effect only for autoland. For manual landing, the regulatory margin included in the required landing distance covers the slope effect.*

L2 For more information about the Required and the Actual Landing Distance, *Refer to PER-LND-GEN Landing Distance Definitions* .

GO-AROUND ALTITUDE

Applicable to: ALL

The GA ALTITUDE field is optional. The display of GA ALTITUDE is at the Airline's discretion.
GA ALTITUDE is a geometrical altitude. The GA ALTITUDE is specific to the selected airport.

GA ALTITUDE is equal to the sum of:
- A go-around height, which is at the Airline's discretion
- The elevation of the runway threshold.

If GA ALTITUDE does not appear on the Airport panel, LDG PERF computes the go-around gradients at an altitude equal to the runway threshold altitude.
If GA ALTITUDE appears on the Airport panel, LDG PERF computes the go-around gradients at an altitude equal to GA ALTITUDE.
The GA ALTITUDE option enables the flight crew to compute go-around gradients at a more operational go-around height.
The higher the GA ALTITUDE, the lower the go-around gradients.

MODIFY RWY SUBPANEL

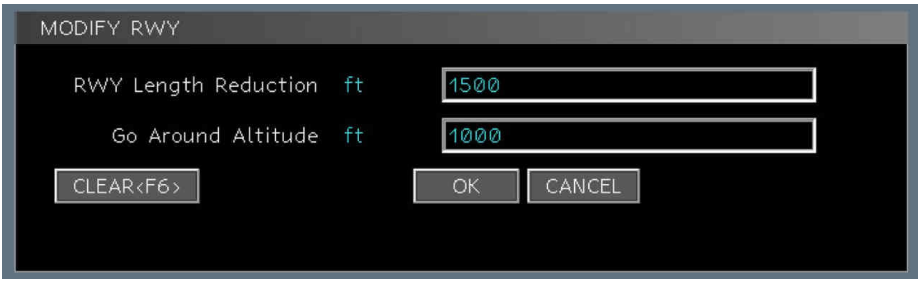
Applicable to: ALL

The flight crew uses the MODIFY RWY subpanel to modify the characteristics of the selected runway by decreasing the runway length or entering the new go-around altitude.

L2 The flight crew can access this subpanel using the MODIFY RWY button of the SINGLE RWY COMPUTATION panel.

For more information about the SINGLE RWY COMPUTATION panel, *Refer to PER-LND-LCD-RWY Airport Panel* .

MODIFY RWY Subpanel



L1 RWY LENGTH REDUCTION

The flight crew can enter the runway length reduction.

The runway length (LENGTH) displayed on the SINGLE RWY COMPUTATION panel is reduced according to the entered value.

The SINGLE RWY COMPUTATION panel displays the label “LENGTH MODIFIED” to indicate that the flight crew has modified the runway length.

GO-AROUND ALTITUDE

The "Go Around Altitude" field is optional and is displayed if this information is available on the SINGLE RWY COMPUTATION panel.

The flight crew can enter a new go-around altitude value.

The go-around altitude (GA ALTITUDE) displayed on the SINGLE RWY COMPUTATION panel is equal to the value entered in the MODIFY RWY Subpanel.

The SINGLE RWY COMPUTATION panel displays the label “GA ALTITUDE MODIFIED” to indicate that the flight crew has modified the go-around altitude.

L2 For more information about the go-around altitude, *Refer to PER-LND-LCF-RWY Go-Around Altitude* .

CREATE RWY - FULL MODE

Applicable to: ALL

FUNCTIONS

The FUNCTIONS drop down list enables the flight crew to:

- MODIFY RWY: To modify the characteristics of an existing runway
- RESTORE RWY: To reset to default values the characteristics of an existing runway after the flight crew has modified it
- CREATE RWY: To create a new runway for an existing airport or for a new airport
- EDIT RWY: To edit the characteristics of the runway that the flight crew has created
- DELETE RWY: To delete a previously created runway.

MODIFY RWY

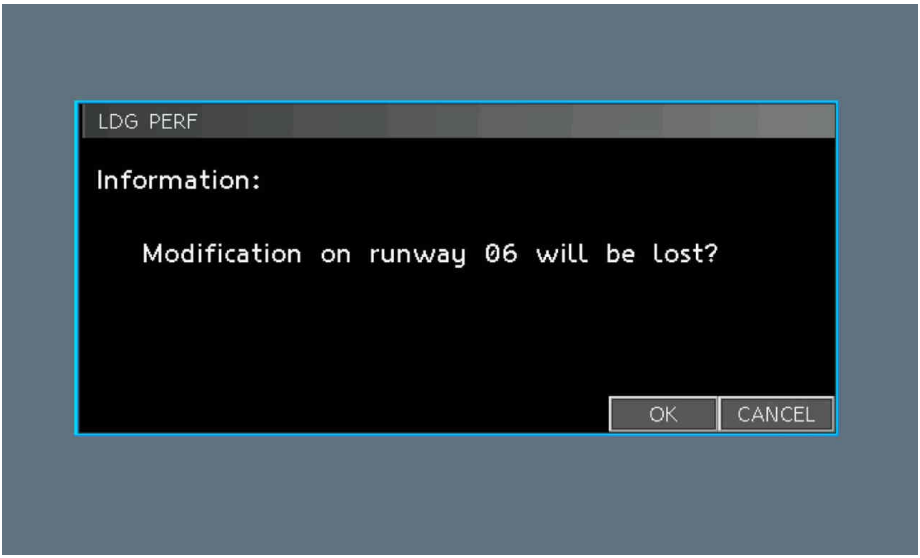
The flight crew uses the RUNWAY MODIFICATION/CREATION panel to modify the characteristics of the selected runway.

L2 The flight crew can access this panel by selecting MODIFY RWY in the FUNCTIONS drop down list of the SINGLE RWY COMPUTATION panel.

RUNWAY MODIFICATION/CREATION Panel

L1 The runway characteristics displayed on the SINGLE RWY COMPUTATION panel are updated according to the entered value.
The SINGLE RWY COMPUTATION panel displays the label “MODIFIED” after the runway ID to indicate that the flight crew has modified the characteristics of the runway. Each modified runway characteristic is displayed with the color cyan.
If a runway has already been created or modified for an airport, and if the flight crew selects MODIFY RWY for another runway of the same airport, a dialog box warns the flight crew that the previous created or modified runway will be lost.

Dialog Box



RESTORE RWY

The flight crew can reset to default values the characteristics of an existing runway after it has been modified.

CREATE RWY

The RUNWAY MODIFICATION/CREATION panel enables the flight crew to:
- Create a new runway for an existing airport, or
- Create a new airport with an associated runway.

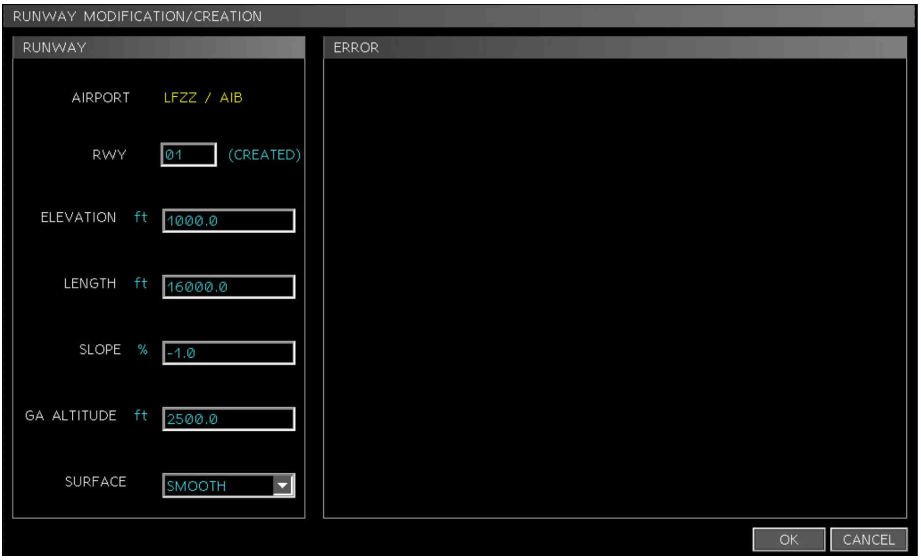
The SINGLE RWY COMPUTATION panel displays the label “CREATED” after the runway ID to indicate that the flight crew has created a new runway.

CREATE A NEW RUNWAY FOR AN EXISTING AIRPORT

To create a new runway for an existing airport, the flight crew:
- First selects an existing airport in the AIRPORT drop down list of the SINGLE RWY COMPUTATION panel, and
- Then selects CREATE RWY in the FUNCTIONS drop down list of the SINGLE RWY COMPUTATION panel.

LDG PERF displays the following panel:

RUNWAY MODIFICATION/CREATION Panel



Note: The field SURFACE appears on the RUNWAY MODIFICATION/CREATION panel. This option should not be available as the A380 has not the grooved runway option capability. The selection of the GROOVED/PFC option does not lead to additional landing benefit. Whatever the SURFACE selection, the LDG PERF calculation considers the SMOOTH SURFACE.

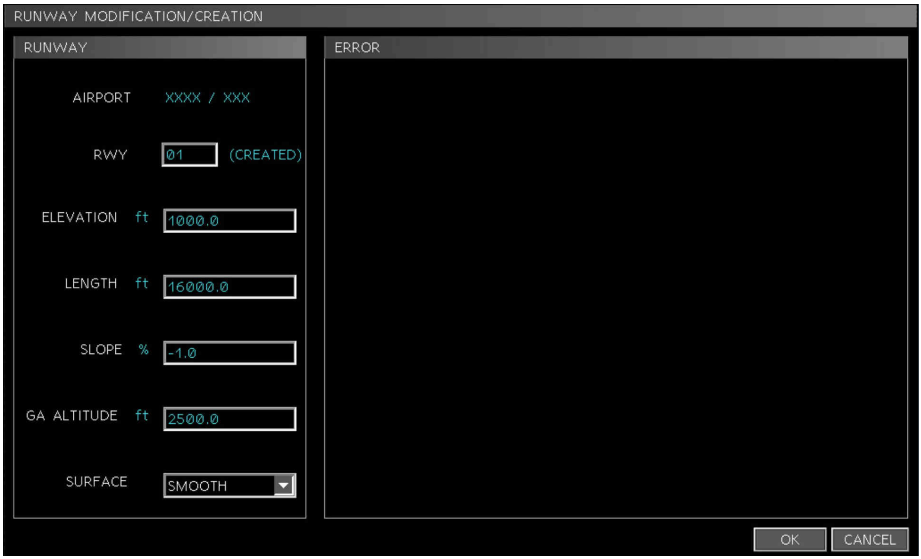
CREATE A NEW AIRPORT WITH AN ASSOCIATED RUNWAY

To create a new airport with an associated runway, the flight crew:

- First checks that the AIRPORT drop down list of the SINGLE RWY COMPUTATION panel is empty, and
- Then selects CREATE RWY in the FUNCTIONS drop down list of the SINGLE RWY COMPUTATION panel.

LDG PERF displays the following panel:

RUNWAY MODIFICATION/CREATION Panel



Note: The field SURFACE appears on the RUNWAY MODIFICATION/CREATION panel. This option should not be available as the A380 has not the grooved runway option capability. The selection of the GROOVED/PFC option does not lead to additional landing benefit. Whatever the SURFACE selection, the LDG PERF calculation considers the SMOOTH SURFACE.

EDIT RWY

When the flight crew has created a new runway, he can then edit the characteristics of this runway.

DELETE RWY

The flight crew can only delete a runway that has been previously created. The flight crew cannot delete the runways already available in the airport database loaded into LDG PERF.
To delete a runway, the flight crew selects DELETE RWY in the FUNCTIONS drop down list of the SINGLE RWY COMPUTATION panel.

MULTIPLE RWY COMPUTATION PANEL

Applicable to: ALL

The flight crew uses the MULTIPLE RWY COMPUTATION panel to select several runways for which computation will be performed in the current conditions.
L2 This function increases calculation time.

MULTIPLE RWY COMPUTATION Panel

L1 AIRPORT SELECTION

The AIRPORT drop-down list provides a list of the available airports.

RUNWAY TABLE

The flight crew uses the runway table to select the runways on which the computation will be performed.

Intentionally left blank

OUTSIDE CONDITIONS SUBPANEL

Applicable to: ALL

The Outside Conditions subpanel provides the following information:

- Wind
- Outside Air Temperature (OAT)
- Pressure at the Mean Sea Level (QNH)
- Runway conditions
- Anti-ice status.

Outside Conditions Subpanel

WIND

Applicable to: ALL

GENERAL

L2 The longitudinal wind component affects the aircraft ground speed, and therefore the landing distances.

L1 The landing distance decreases in the case of headwind, and increases in the case of tailwind.

L2 In the case of headwind, the Approach Speed (VAPP) must additionally be increased to avoid speed loss close to the ground, since wind speed is often reducing as the aircraft descends. As a result, the beneficial headwind effect on the landing distance is compensated for by the increase of the Approach Speed (VAPP).
As per regulation, the computation is based on 150 % of the entered tailwind, and 50 % of the entered headwind.

L1 The crosswind component does not affect the calculation of the landing distance. However, a maximum crosswind component is demonstrated.
For more information about crosswind limitation, *Refer to PER-LND-CTA-CWD Crosswind* .

LDG PERF

There are two ways to define wind values:
- Longitudinal Speed Component
- Direction/Speed (or Direction/Speed/Gust) Combination.

The Direction/Speed (or Direction/Speed/Gust) Combination is required in the case of a MULTIPLE RUNWAY COMPUTATION.

Note: *Displayed wind values are rounded mathematically instead of conservatively, but there is no impact on the computation, which uses exact values.*

LONGITUDINAL SPEED COMPONENT

The flight crew enters the longitudinal component with:
- H or HD followed by the headwind speed (e.g. H10 or HD5), or
- T or TL followed by the tailwind speed (e.g. T6 or TL8).

Wind Values Input - Longitudinal Speed Component

DIRECTION/SPEED (OR DIRECTION/SPEED/GUST) COMBINATION

This wind input mode is compulsory when computations are made on multiple runways.

The flight crew can enter:
- The wind direction and the wind speed, or
- The wind direction, the wind speed, and the gust, if this option is enabled.

Direction/Speed Combination

The speed entry is projected along the runway axis and perpendicular to the runway axis. The longitudinal projection follows the same display rules as the longitudinal speed component entry mode.

LDG PERF displays the crosswind as:
- R, if the wind comes from the right, or
- L, if the wind comes from the left.

Wind Values Input - Direction/Speed Combination

Direction/Speed/Gust Combination

This entry mode is possible if a maximum crosswind limit is defined as gust included for one RWY COND at least.

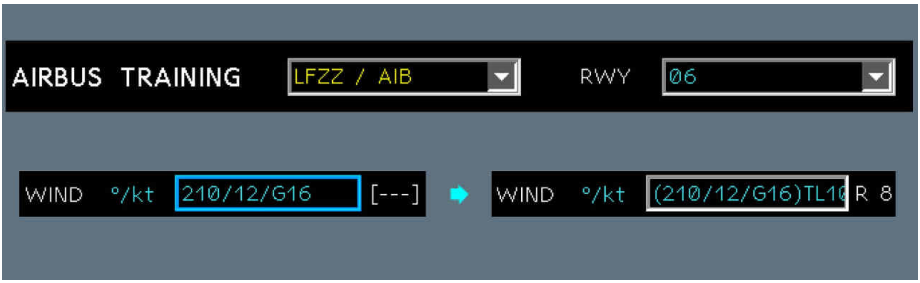
In this case, the flight crew can enter the value of the gust with the prefix G followed by the gust value (e.g. G16).
The speed entry (gust respectively) is projected along the runway axis and perpendicular to the runway axis.
The longitudinal projection follows the same display rules as the longitudinal speed component entry mode.

LDG PERF displays the crosswind as:
- R, if the wind comes from the right, or
- L, if the wind comes from the left.

If the flight crew enters the gust, LDG PERF displays the perpendicular projection of the gust as the crosswind.

LDG PERF uses:
- The gust perpendicular component for the check of the maximum crosswind limitation if this one is defined as gust included for the selected RWY COND
- The steady wind perpendicular component for the check of the maximum crosswind limitation if this one is not defined as gust included for the selected RWY COND.

Wind Values Input - Direction/Speed/Gust Combination



OUTSIDE AIR TEMPERATURE

Applicable to: ALL

GENERAL

The Outside Air Temperature (OAT) affects the go-around performance.

Note: As per regulation, the effect of temperature on landing distance is only taken into account for water contaminated runway or autoland.

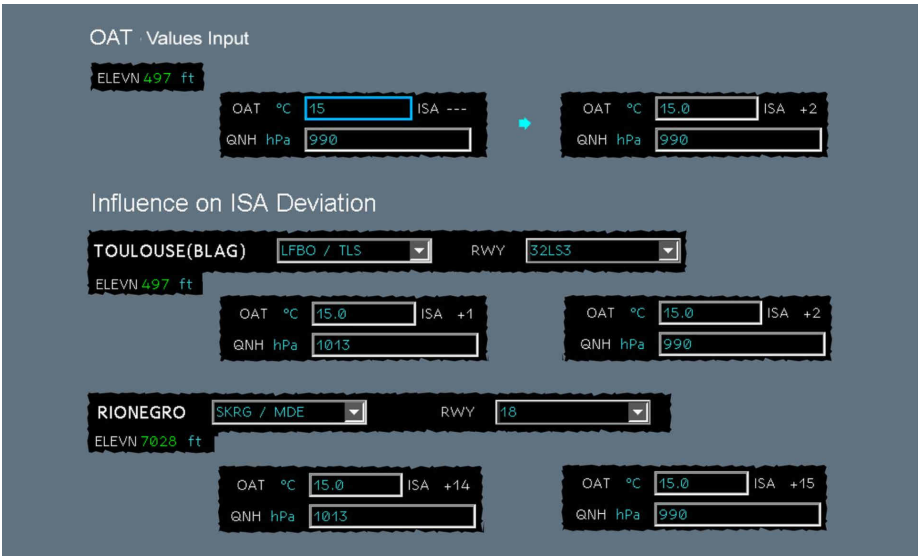
TEMPERATURE EFFECT ON ENGINE THRUST

The thrust provided by the engines at go-around rating (TOGA) versus OAT is constant up to the flat rating temperature (TREF).

When the OAT increases,
- The available engine thrust decreases above TREF
- The go-around climb gradients decrease.

LDG PERF

OAT Input



OAT VALUE INPUT

The OAT is the input parameter that gives the temperature at the arrival airport.

L2 The range of permitted OAT is the certified environmental envelope for landing, which depends on the airport pressure altitude and the runway condition.

L1 The deviation from the International Standard Atmosphere (ISA) is automatically computed and displayed next to the OAT field.

INFLUENCES ON ISA DEVIATION

The deviation from ISA is influenced by:

- The airport elevation
- The QNH value.

L2 For more information about the QNH , *Refer to PER-LND-LCF-OCD QNH* .

QNH

Applicable to: ALL

GENERAL

The QNH is the pressure at the Mean Sea Level (MSL).

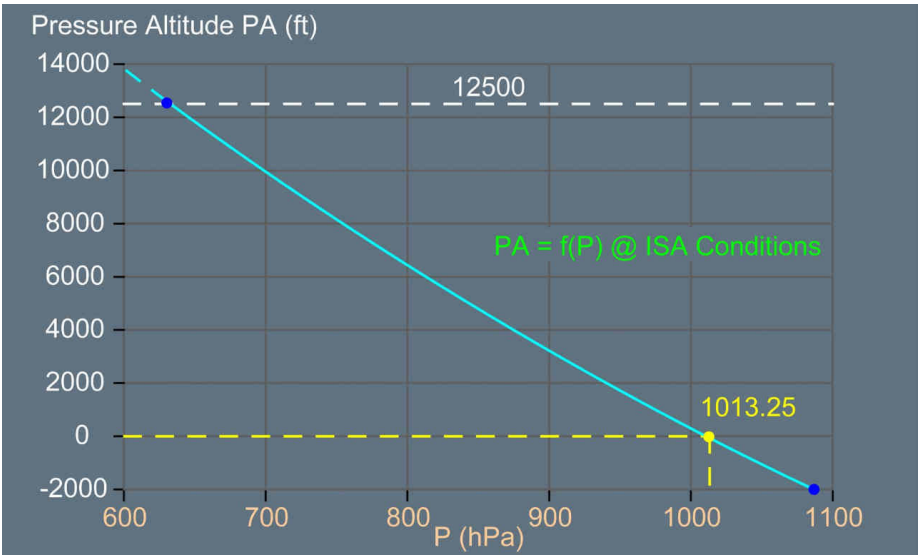
L2 The QNH is calculated from:
- The airport atmospheric pressure
- The airport elevation
  The airport elevation is the geometric altitude of the airport.
- The standard pressure law from ISA atmosphere.

At the airport level, with the QNH setting, in ISA conditions, the altimeter indicates the airport elevation.

L1 The airport Pressure Altitude (PA) depends on the QNH and the airport elevation.

L2 The PA is a barometric measurement converted into an altitude via the ISA law.

PA Function of Pressure (P)



L1 The QNH affects the aircraft landing speed and engine thrust.

QNH EFFECT ON LANDING SPEED

When the QNH decreases at a given airport elevation:
- The PA increases
- The air density ρ decreases
- A higher TAS is required for approach in order to maintain the same lift
- The landing distance is longer.

QNH EFFECT ON ENGINE THRUST

When the QNH decreases at a given airport elevation:
- The PA increases
- The available engine thrust decreases
- The landing distance increases
- The go-around climb gradients decrease.

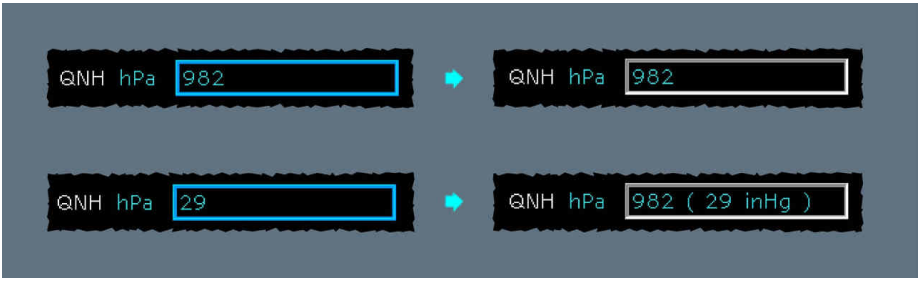
LDG PERF

The QNH is the input parameter that determines the pressure altitude, taking into account the airport elevation.

The flight crew can enter a QNH using the following units:
- Hecto Pascal (hPa)
- Inch of Mercury (inHg).

LDG PERF automatically detects the QNH format. For example, when the flight crew enters 29 for the QNH, LDG PERF automatically converts the value into the appropriate one for hPa unit.

QNH Input



The QNH range is:
- 950 - 1080 for hPa
- 28.06 - 31.89 for inHg.

RUNWAY CONDITIONS

Applicable to: ALL

GENERAL

The runway surface condition affects the landing performance and must be taken into account for MLW(PERF) calculation.
For more information about the runway conditions, *Refer to Runway Contamination* .

LDG PERF

The flight crew selects one of the following settings from the RWY COND drop-down list depending on the runway surface condition.

DRY

The flight crew selects “Dry” for dry runways.

WET

The flight crew selects “Wet” for runways covered with:
- Less than 0.12 in of Water, or
- Equivalent contaminants in terms of performance:
  - Less than 0.12 in of Slush, or
  - Less than 0.16 in of Wet Snow, or
  - Less than 0.59 in of Dry Snow.

For more information about equivalences, *Refer to PER-LND-CTA Equivalences for Performance* .

WATER 1/4" (6.3 MM)

The flight crew selects ”Water 1/4” (6.3 mm)” between 0.12 in and 0.50 in of Standing Water.
L2 For landing performance assessment, a higher contaminant depth systematically produces shorter landing distances. Airports tend to overestimate contaminant thicknesses in their reporting. This may result in a calculated landing distance shorter than the achievable one. As a consequence, Airbus does not recommend the operational use of the landing distance information corresponding to the "Water 1/2" (12.7 mm)" and "Slush 1/2" (12.7 mm)".

L1 SLUSH 1/4" (6.3 MM)

The flight crew selects “Slush 1/4" (6.3 mm)” for runways covered with:
- Between 0.12 in and 0.50 in of Slush, or
- Equivalent contaminants in terms of performance:
  - Between 0.16 in and 1.00 in of Wet Snow, or

- Between 0.59 in and 4.00 in of Dry Snow.

For more information about equivalences, *Refer to PER-LND-CTA Equivalences for Performance* .

L2 For landing performance assessment, a higher contaminant depth systematically produces shorter landing distances. Airports tend to overestimate contaminant thicknesses in their reporting. This may result in a calculated landing distance shorter than the achievable one. As a consequence, Airbus does not recommend the operational use of the landing distance information corresponding to the "Water 1/2" (12.7 mm)" and "Slush 1/2" (12.7 mm)".

L1 **COMPACTED SNOW**

The flight crew selects “Compacted snow” for runways covered with Compacted Snow.

ICY

The flight crew selects "Icy" for runways covered with ice.

CAUTION	Landing on icy runway is not recommended.

ANTI-ICE

Applicable to: ALL

GENERAL

The engine bleed air system supplies high-pressure air to the following systems:
- Air conditioning and cabin pressurization
- Wing anti-ice and engine anti-ice
- Engine start
- Hydraulic reservoir pressurization
- Pack bay ventilation system.

L2 For more information about the engine bleed air system, *Refer to DSC-36-10-20-10 Engine Bleed Air System* .

L1 The air conditioning and the anti-ice (wing, engine) systems affect the landing performance. The engine bleeds reduce the available engine power. As a result, the go-around gradient decreases. The FADEC compensates to a large extent the thrust loss due to “Engine only” anti-ice.

LDG PERF

The flight crew selects one of the following setting from the A-ICE drop-down list:
- Off
- Engine only
- Engine & Wing.

AIRCRAFT CONFIGURATION SUBPANEL

Applicable to: ALL

The Aircraft Configuration subpanel provides the following information:

- Landing weight (LW)
- Aerodynamic configuration
- Airflow
- Approach type
- Go-around gradient
- Approach speed
- Landing technique
- Braking mode.

Aircraft Configuration Subpanel

LANDING WEIGHT

Applicable to: ALL
Impacted by TDU: 00021447 Landing Weight

GENERAL

The estimated Landing Weight (LW) in flight must not exceed:

- The certified Maximum Takeoff Weight (MTOW)

L2 The landing calculation at a weight above MLW and below MTOW takes into account overweight conditions.
For more information about overweight procedures, *Refer to PRO-ABN-ECAM-10-80-50 MISC OVERWEIGHT LDG* .

L1
- MLW(PERF) .

L2 For more information about MLW(PERF) , *Refer to PER-LND-LRF-FSR Landing Weights* .

L1 LDG PERF

The flight crew can enter:

- The estimated LW value, or

L2 The LW entered must be less than the certified MTOW , as per operator policy.

L1
- The shortcut "*", to insert the MLW , or
- A weight that is more than the MLW .

The results will be displayed for the weight entered, regardless of the MLW . In this case, the warning message "OVERWEIGHT LANDING" appears at the top of the RESULTS panel.

COMMUNICATION FROM LOADSHEET TO LDG PERF

When the flight crew completes a LOADSHEET computation and then changes from LOADSHEET to LDG PERF, LOADSHEET transfers the calculated LW value to LDG PERF. LDG PERF displays this value in yellow in the CONDITIONS panel.

LANDING WEIGHT

Applicable to: ALL
Impacted DU: 00011674 Landing Weight

GENERAL

The estimated Landing Weight (LW) in flight must not exceed:

- The certified Maximum Takeoff Weight (MTOW)

L2 The landing calculation at a weight above MLW and below MTOW takes into account overweight conditions.
For more information about overweight procedures, *Refer to PRO-ABN-ECAM-10-80-50 MISC OVERWEIGHT LDG* .

L1 - MLW(PERF) .

L2 For more information about MLW(PERF) , *Refer to PER-LND-LRF-FSR Landing Weights* .

L1 LDG PERF

The flight crew can enter:

- The estimated LW value, or

L2 The LW entered must be less than the certified MTOW , as per operator policy.

L1 - The shortcut "*", to insert the MLW , or
- A weight that is more than the MLW .
The results will be displayed for the weight entered, regardless of the MLW . In this case, the warning message "OVERWEIGHT LANDING" appears at the top of the RESULTS panel.

COMMUNICATION FROM LOADSHEET TO LDG PERF

When the flight crew completes a LOADSHEET computation and then changes from LOADSHEET to LDG PERF, LOADSHEET transfers the calculated LW value to LDG PERF. LDG PERF displays this value in yellow in the CONDITIONS panel.

Note: When both LOADSHEET and LDG PERF are opened, LDG PERF always takes the landing weight from the LOADSHEET results.
Check the landing weight in LDG PERF before any calculation, particularly in the case of a diversion.

CG POSITION

Applicable to: ALL

GENERAL

The Center of Gravity (CG) position affects the balance of forces applied on the aircraft. As a result, the CG position affects the aircraft performance, particularly the Approach Speed (VAPP) and the go-around speed.

L2 The CG position has a direct effect on the stalling speeds. A forward CG increases the stalling speeds and an aft CG reduces them. Therefore, the CG position affects the VAPP and the go-around speed and thus the entire landing performance.

L1 LDG PERF

The CG field is expressed in % of the Mean Aerodynamic Chord (MAC).
In accordance with aircraft certification, and without failure in flight, the CG is assumed to be at the most forward limit for all computations. The CG field does not appear on the CONDITIONS panel.
In the case of the selection of a failure in flight, the CG field becomes available on the CONDITIONS panel, in order to reduce conservatism on the approach speed in such a degraded situation. The VAPP computation takes into account the value that the flight crew enters in the CG field, but the landing distance computation considers that the CG is at the most forward limit.

L2 For more information about the CG in the case of a failure in flight, *Refer to Landing Performance Following Failure - Impact on Conditions* .

AERODYNAMIC CONFIGURATION

Applicable to: ALL

GENERAL

The certified landing configurations are:
- CONF 3
- CONF FULL.

CONF FULL is recommended.
The selection of an aerodynamic configuration affects the landing performance.
L2 At a given speed, a higher flap setting increases the lift, but also increases the drag. Therefore, a higher flap setting decreases the landing distance, but also decreases the go-around gradient.

L1 LDG PERF

LDG PERF provides two types of calculation related to the aerodynamic configuration:
- For a given flap setting (CONF 3, CONF FULL)
- AUTO CONF.

When the flight crew selects AUTO CONF, LDG PERF computes the landing performance for:
- Landing in CONF FULL (go-around in CONF 3)
- Landing in CONF 3 (go-around in CONF 2).

If both a go-around in CONF 3 (landing in CONF FULL) and a go-around in CONF 2 (landing in CONF 3) comply with the go-around gradient constraint, then LDG PERF displays the results for: landing in CONF FULL (go-around in CONF 3).
If a go-around in CONF 3 (landing in CONF FULL) does not comply with the go-around gradient constraint, the flight crew lands in CONF 3 and performs go-around in CONF 2. LDG PERF displays the results for: landing in CONF 3 (go-around in CONF 2).

OVERWEIGHT LANDING

In the case of an overweight landing, when the flight crew selects AUTO CONF, LDG PERF will also compute landing performance in CONF 3 (go-around in CONF 1+F) if a go-around in CONF 2 does not comply with the go-around gradient constraint.

ECAM ALERTS

When an ECAM Alert item is selected, the selection of an aerodynamic configuration in the CONDITIONS panel of LDG PERF is not possible any more. For all ECAM Alerts, the aerodynamic configuration is automatically determined according to the failure.

GO-AROUND CONFIGURATION

Applicable to: ALL

GA CONF on the CONDITIONS panel is the flaps setting to be used for the go-around. GA CONF only appears in the case of an overweight landing.

When the flight crew sets the LDG CONF drop down list to:
- AUTO CONF, GA CONF is automatically set to AUTO CONF. LDG PERF determines the go-around configuration depending on the landing performance calculation
- CONF FULL, GA CONF is automatically set to CONF 3
- CONF 3, the flight crew can select CONF 2 or CONF 1+F for GA CONF.

AIRFLOW

Applicable to: ALL

GENERAL

The engine bleed air system supplies high-pressure air to the following systems:
- Air conditioning and cabin pressurization
- Wing anti-ice and engine anti-ice
- Engine start
- Hydraulic reservoir pressurization
- Pack bay ventilation system.

L2 For more information about the engine bleed air system, *Refer to DSC-36-10-20-10 Engine Bleed Air System* .

L1 The air conditioning and the anti-ice (wing, engine) systems affect the landing performance. The engine bleeds reduce the available engine power. As a result, the go-around gradient decreases.

LDG PERF

The flight crew selects one of the following setting from the AIR COND drop-down list:
- On
- Off.

APPROACH TYPE

Applicable to: ALL

GENERAL

As the A380 is a four-engined aircraft, the approach type does not affect the minimum go-around gradient (2.7 %).

L2 The CAT II minimum go-around gradient (2.5 %) is lower than the CAT I minimum go-around gradient (2.7 %) for a four-engined aircraft.

L1 The approach type affects the go-around speed for the approach climb calculation:

- For CAT I approach type: The go-around speed is equal to VLS (1.23 VS1G) of the approach configuration
- For CAT II approach type: The go-around speed is equal to the maximum of:
  - VLS of the approach configuration (landing gear retracted)
  - VLS of the landing configuration (landing gear extended) + 5 kt
  - Minimum Control Airspeed for Landing (VMCL) + 5 kt.

As a result, the approach type only affects the approach climb gradient calculation.

LDG PERF

The flight crew selects one of the following approach types:

- Normal, for a CAT I approach
- CAT II, for a CAT II or a CAT III approach.

GO-AROUND GRADIENT

Applicable to: ALL

GENERAL

As per regulation the aircraft must achieve the minimum go-around gradient which is the maximum of:

- 2.7 %
- The value published in the go-around procedure.

L2 For more information about the go-around gradient, *Refer to PER-LND-LRF-FSR Go-Around Gradient* .

L1 LDG PERF

The flight crew can use the shortcut "MIN" to insert the minimum regulatory go-around gradient value.

To compute with a go-around gradient more than the minimum one, the flight crew enters the required gradient in GA GRADIENT.

USER SPEED INCREMENT - VLS+ / VPILOT

Applicable to: ALL

GENERAL

The Approach Speed (VAPP) is the speed of the aircraft when crossing the runway threshold.

VAPP is the sum of:

- VLS

L2 VLS is the Lowest Selectable Speed
VLS is equal to 1.23 VS1G

L1 - The wind speed increment

L2 The wind correction is equal to 1/3 of the headwind. The wind correction is limited to 15 kt .
When A/THR is selected, a minimum wind correction of 5 kt is required.

L1 - The CDL speed increment
- The ECAM Alert speed increment
- An extra value selected at the flight crew discretion.

LDG PERF

NO ECAM ALERT ITEM SELECTED - VLS+

The default value of the increment on the approach speed field (VLS+) is equal to the wind speed increment, considering that the A/THR is ON.
The flight crew can increase the default value of the increment on the approach speed.

When the flight crew starts a computation, LDG PERF computes the landing performance with an approach speed equal to the sum of:

- VLS
- The user speed increment
- The CDL speed increment, if the flight crew has selected a CDL item that affects the approach speed.

L2 For more information about the CDL items, *Refer to PER-LND-LCF-AFS CDL* .

L1 ECAM ALERT ITEM SELECTED - VPILOT

VPilot only appears if an ECAM Alert item is ticked in the ECAM ALERTS panel of LDG PERF.
The default value of VPilot is zero. It considers that the A/THR is OFF.
The flight crew can enter an airspeed correction in VPilot to increase the approach speed.

L2 For more information about:

- VPilot determination, *Refer to PER-LND-LFF-CMT VPilot Determination for VAPP Calculation* .
- LDG PERF calculation sequence using the VPilot airspeed correction, *Refer to PER-LND-LFF-CMT Calculation Sequence* .

L1 When the flight crew starts a computation, LDG PERF computes the landing performance with an approach speed equal to the sum of:
- VLS
- VPilot
- The wind speed increment

L2 The wind correction is equal to 1/3 of the headwind. The wind correction is limited to 15 kt .

L1
- The CDL speed increment, if the flight crew has selected a CDL item that affects the approach speed
- The ECAM Alert speed increment, in the case of the selection of an ECAM Alert item that affects the approach speed.

LANDING TECHNIQUE

Applicable to: ALL

GENERAL

The autoland systems are designed to help the flight crew for landing in low visibility.

L2 On a dry runway the Actual Landing Distance (ALD) in autoland is the addition of two distances: the airborne phase distance and the ground phase distance.

L1 LDG PERF

The flight crew selects one of the following setting in the LDG TECHNIQUE drop-down list:
- Autoland
- Manual.

When Autoland is selected, the flight crew must enter the glide slope angle.

BRAKING MODE

Applicable to: ALL

GENERAL

To brake the aircraft, the flight crew can use:
- The manual braking via the brake pedals
- The automatic braking via the autobrake system.

L2 For more information about the use of the autobrake system, *Refer to PER-LND-GEN Use of the Autobrake System* .

L1 LDG PERF

The flight crew selects one of the following braking mode:
- Manual
- Lo
- 2
- 3
- Hi.

For Manual braking mode, LDG PERF considers that:
- The flight crew applies the braking at the touchdown of the main landing gear
- The braking is the maximum braking performance limited by the Anti-Skid (A-SKID).

If the flight crew selects an ECAM Alert, then only the Manual braking mode is available for computation.

Intentionally left blank

AIRCRAFT STATUS PANEL

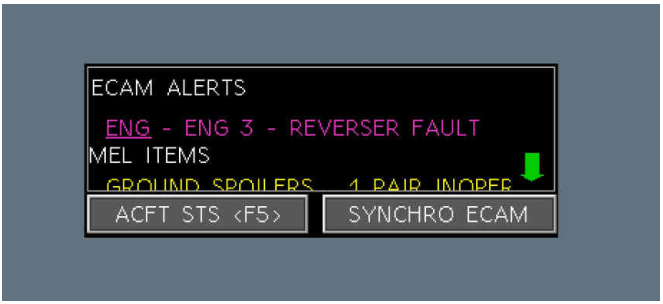
Applicable to: ALL

The current aircraft status must be considered for the computation.

The reminder area of the AIRCRAFT STATUS panel lists:
- ECAM alerts impacting landing performance
- Inoperative systems impacting landing performance
- The number of MEL items without landing performance impact (if any)
- CDL items impacting landing performance
- The number of negligible CDL items (if any).

If no ECAM Alert affects landing performance and if the aircraft is dispatched without any deferred items, "NO PERFORMANCE IMPACT" appears in the reminder area of the AIRCRAFT STATUS panel.

Reminder area of the AIRCRAFT STATUS Panel



SYNCHRO ECAM

The flight crew can retrieve the ECAM alerts affecting landing performance by clicking on the "SYNCHRO ECAM" button.
For more information about the SYNCHRO ECAM function, *Refer to PER-LND-LCF-AFS Synchronization with ECAM* .

AIRCRAFT STATUS

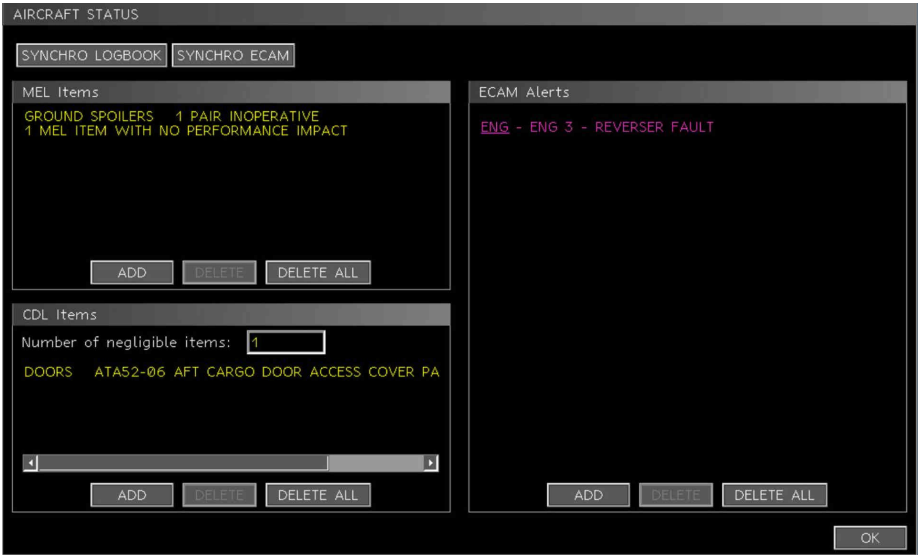
By clicking on the ACFT STS button, the flight crew opens the AIRCRAFT STATUS panel.

The AIRCRAFT STATUS panel is divided in three subpanels:
- MEL items
- CDL items
- ECAM Alerts.

Moreover, the flight crew can:

- Recover the eLogbook status by clicking on the "SYNCHRO LOGBOOK" button
- Retrieve the ECAM alerts affecting landing performance by clicking on the "SYNCHRO ECAM" button.

AIRCRAFT STATUS Panel



MEL

Applicable to: ALL

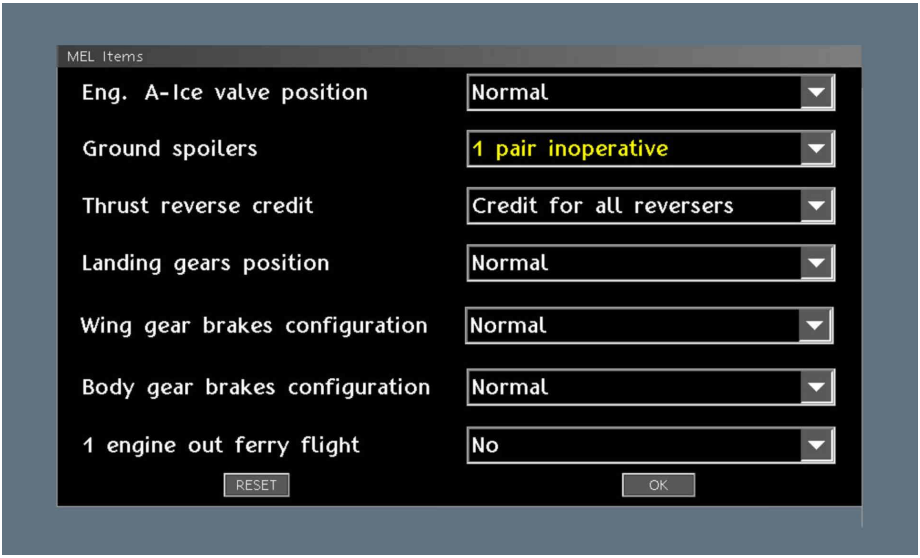
The MEL items subpanel displays the inoperative systems selected by the flight crew using:

- The OPS LIBRARY / MEL manual, via the selection of a MEL item, or
  In this case, the inoperative systems are displayed in yellow on LDG PERF.
- The LDG PERF MEL panel.
  In this case, the inoperative systems are displayed in cyan on LDG PERF.

MEL ITEM SELECTION

To open the MEL items panel, the flight crew uses the ADD button of the MEL items subpanel.
The MEL items panel displays the list of systems that could be inoperative and that involve landing performance penalties.
The flight crew selects inoperative items by selecting the appropriate status for each item in the drop-down lists.
The inoperative system associated to the MEL item is described in the (o) procedure of the MEL item.

MEL Items Panel



The selected item appears in the MEL items subpanel and in the reminder area of the AIRCRAFT STATUS panel.

COMMUNICATION BETWEEN MEL MANUAL AND LDG PERF

When the aircraft is dispatched with MEL items and if these MEL items are selected via the OPS LIBRARY / MEL manual:

- The associated inoperative systems that affect the landing performance are automatically selected and displayed in yellow on the reminder area of the AIRCRAFT STATUS panel in LDG PERF
- The number of MEL items without landing performance impact is displayed in yellow on the reminder area of the AIRCRAFT STATUS panel in LDG PERF.

CDL

Applicable to: ALL

The CDL items subpanel displays the missing structural parts selected by the flight crew using:

- The OPS LIBRARY / CDL manual, via the selection of a CDL item, or
  In this case, the CDL items are displayed in yellow on LDG PERF.
- The LDG PERF CDL panel.
  In this case, the CDL items are displayed in cyan on LDG PERF.

The CDL items subpanel also displays the number of negligible items.

NUMBER OF NEGLIGIBLE ITEMS

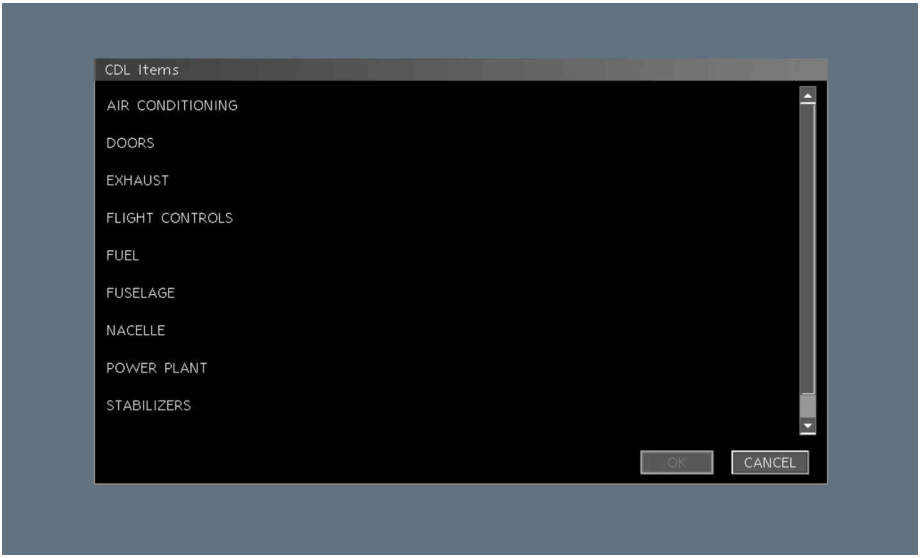
The flight crew enters the number of different structural parts simultaneously missing that have a negligible impact on the performance.

L2 If the number of negligible items is less or equal to three, there is no performance penalty. If the number of negligible items is greater or equal to four, then a drag increase for each item is taken into account for the performance computation.
For more information about the negligible CDL items, *Refer to AFM/MCDL-GEN-PERF Performance penalties published in the Airplane Flight Manual MCDL chapter*.

L1 CDL ITEM SELECTION

To open the CDL items panel, the flight crew uses the ADD button of the CDL items subpanel. The CDL items panel displays the list of structural parts that could be missing and that involve landing performance penalties.

CDL items Panel



To add a CDL item, the flight crew selects:
- The appropriate system group
- The corresponding CDL item
- The number of items missing

The selected item appears in the CDL items subpanel and in the reminder area of the AIRCRAFT STATUS panel.

Note: *When the flight crew selects a CDL item, the number of missing items is hidden in the ACFT STS box. The flight crew must use the scroll bar to display the hidden information.*

COMMUNICATION BETWEEN CDL MANUAL AND LDG PERF

When the aircraft is dispatched with CDL items and if these CDL items are selected via the OPS LIBRARY / CDL manual:
- The CDL items that affect the landing performance are automatically selected and displayed in yellow on the reminder area of the AIRCRAFT STATUS panel in LDG PERF. Their associated number of missing parts is also displayed.
- The number of CDL items without landing performance impact is displayed in yellow on the reminder area of the AIRCRAFT STATUS panel in LDG PERF. These CDL items are called "negligible items".

When the flight crew uses the OPS LIBRARY / CDL manual to select a specific CDL item that affects the landing performance and then starts LDG PERF, the landing performance module may consider this CDL item as a negligible item if the CDL To LDG PERF communication file does not include this CDL item.
In this case, the flight crew must manually apply the weight reduction described in the OPS LIBRARY / CDL manual to the MLW(PERF) calculated by LDG PERF.

IMPACT ON OUTPUT (WHEN NO ECAM ALERT)

The selection of a CDL item modifies the layout of the RESULTS panel if:
- The CDL item has an impact on the VAPP, and
- No ECAM alert item is selected.

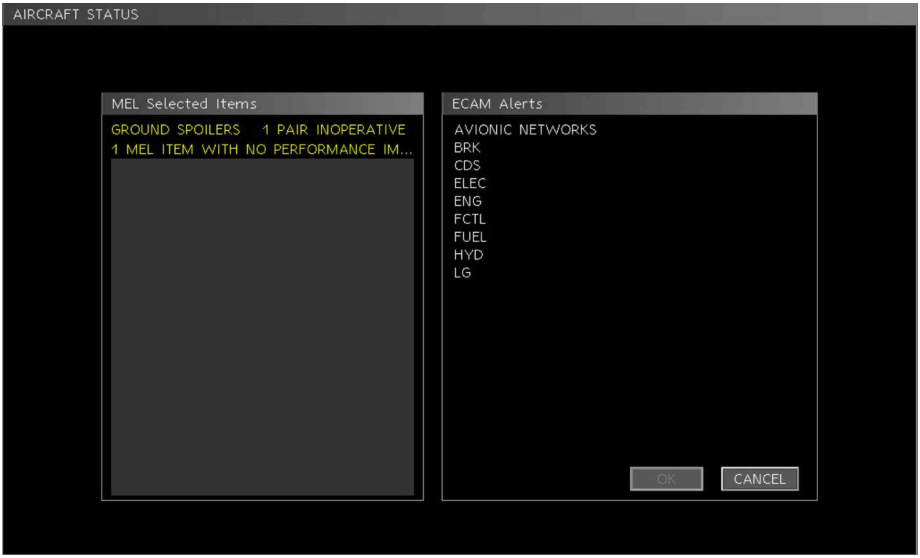
An additional result ΔVCDL appears. ΔVCDL is the speed increment in VAPP due to the selected CDL item(s).

Only the following CDL item induces a speed increment in VAPP:
- POWER PLANT ATA71-15 NACELLE STRAKES
  For more information on this CDL item, *Refer to AFM/MCDL-71-15 Nacelle strake*.
- FLIGHT CONTROLS ATA27-22 FLAP END SEAL.
  For more information on this CDL item, *Refer to AFM/MCDL-27-22 Flap end seal*.

ECAM ALERTS

Applicable to: ALL

ECAM Alerts Panel



SELECTION OF INOPERATIVE ITEMS

The ECAM Alerts panel displays a list of possible inoperative systems that result in an Abnormal or Emergency situation.
This list only includes the ECAM alerts that involve landing performance penalties.
To open the ECAM Alerts panel, the flight crew uses the ADD button of the ECAM Alerts subpanel.

To add an ECAM alert item, the flight crew selects:
- The appropriate system group
- The corresponding ECAM alert item
- The OK button.

The selected item appears in the ECAM Alerts subpanel and in the reminder area of the AIRCRAFT STATUS panel.

Note: *The following error message appears if the flight crew selects the LDG TECHNIQUE Autoland: "Computation using autoland with ECAM Alert is not possible".*
The selection of an ECAM alert item plus the LDG TECHNIQUE Autoland is not possible even if the associated ECAM alert enables the use of the Autoland system.
However, for these failure cases, the distance computed for Manual Landing is consistent with the average landing distance achieved with Autoland.
Therefore, the flight crew can set the LDG TECHNIQUE field to Manual.

COMMUNICATION BETWEEN ECAM AND LDG PERF

The ECAM alert items displayed on the ECAM STATUS MORE page are automatically sent to LDG PERF.
For more information about the synchronization with the ECAM , *Refer to PER-LND-LCF-AFS Synchronization with ECAM* .

Note: *In the case of a dispatch with a MEL item that results from an ECAM alert affecting the landing performance during the previous flight, the list of the ECAM alert items is still on the STATUS MORE page of the SD . The list of the ECAM alert items of the previous flight is sent to LDG PERF.*

Workaround:
- *If there is no additional ECAM alert during the current flight: Manually deselect the list of the ECAM alert items in LDG PERF*
- *If there are additional ECAM alerts during the current flight: Deselect the list of the ECAM alert items in LDG PERF that are associated with the MEL dispatch.*

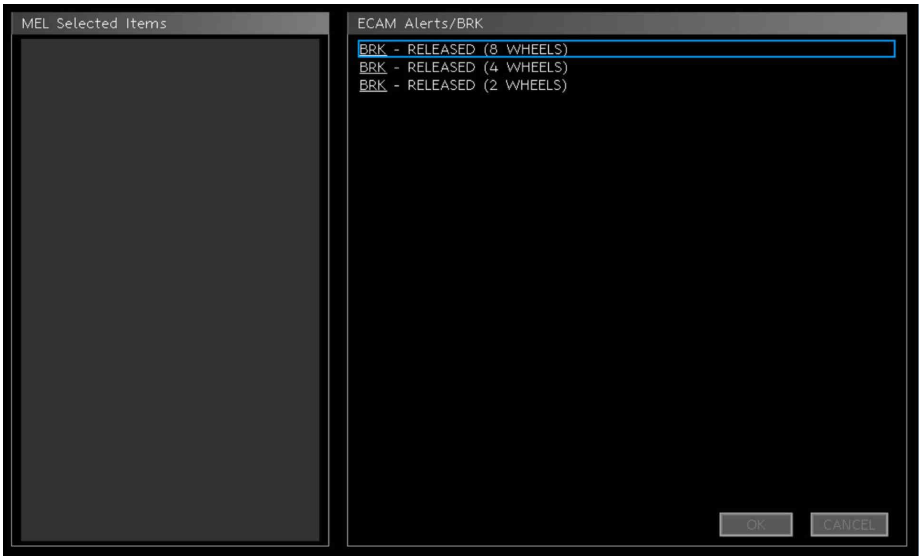
STRICT MATCHING BETWEEN THE ECAM AND LDG PERF

In the case of an automatic or a manual synchronization with the ECAM , and if the ECAM alert displayed on the ECAM STATUS MORE page corresponds to a unique ECAM alert item in LDG PERF, this ECAM alert item directly appears in magenta on the reminder area of the AIRCRAFT STATUS panel, without any flight crew selection.

SEVERAL POSSIBILITIES IN LDG PERF FOR ONE ALERT IN THE ECAM

In the case of an automatic or a manual synchronization with the ECAM , and if the ECAM alert displayed on the ECAM STATUS MORE page may correspond to several possibilities of ECAM alert items in LDG PERF, the flight crew has to manually select the applicable item from a filtered list.
The following type of window is displayed:

ECAM Alerts - Filtered List

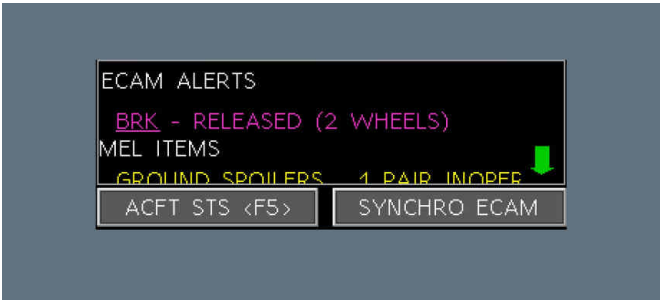


The filtered ECAM alert items correspond to the same ECAM alert on the ECAM STATUS MORE page.

However, the impacts of the filtered ECAM alert items on the landing performance differ by:
- The current or reachable aerodynamic configuration for landing (SLATS LOCKED, SLATS SYS 1+2 FAULT, FLAPS LOCKED, FLAP SYS 1+2 FAULT, G+Y SYST PRESS LO, FLAPS LEVER JAMMED), or
- The number of wheels released (BRAKES RELEASED).

When the flight crew selects the applicable ECAM alert item from the filtered list, this ECAM alert item appears in magenta on the reminder area of the AIRCRAFT STATUS panel.

Reminder area of the AIRCRAFT STATUS panel



IMPACT ON INPUT

The selection of an item in the ECAM Alerts panel modifies the CONDITIONS panel.
For more information about the modifications of the interface, *Refer to PER-LND-LFF-IOI Conditions* .

SYNCHRONIZATION WITH LOGBOOK

Applicable to: ALL

The flight crew can use the "SYNCHRO LOGBOOK" button to recover the eLogbook status.
This action synchronizes the aircraft status of the whole FLT OPS domain with the current deferred items of the eLogbook
If the flight crew had previously selected additional MEL and CDL items in LDG PERF (displayed in cyan in the AIRCRAFT STATUS panel) and then uses the SYNCHRO LOGBOOK function, these manually entered items are lost.

Note:
1. *When the flight crew uses the SYNCHRO LOGBOOK function in LDG PERF, the whole FLT OPS domain is also synchronized with the eLogbook*
2. *If the Logbook status is lost in the FLT OPS domain, LDG PERF may synchronize with an old eLogbook status*
3. *When the flight crew uses the SYNCHRO LOGBOOK function in the IN-FLIGHT Mode of LDG PERF, the ECAM status is also updated.*

SYNCHRONIZATION WITH ECAM

Applicable to: ALL

MANUAL SYNCHRONIZATION WITH THE ECAM: "SYNCHRO ECAM"

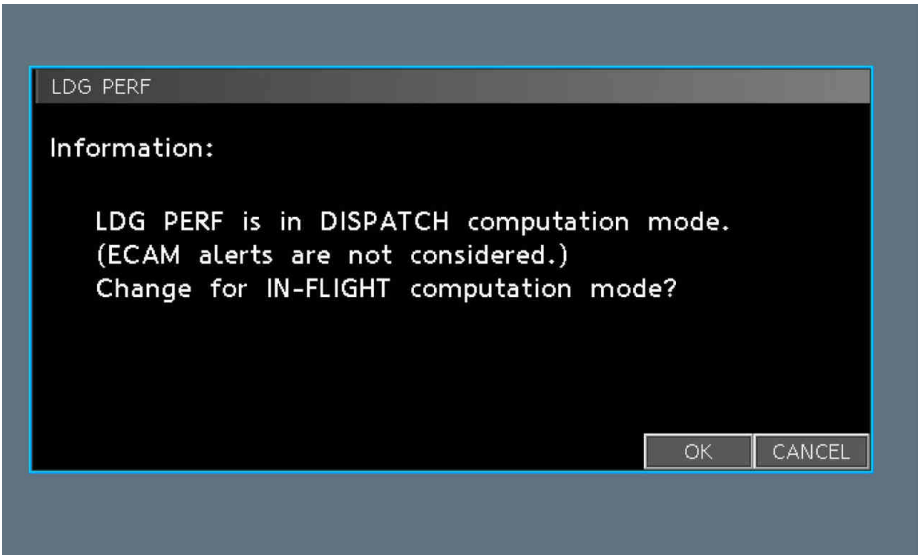
The flight crew can use the "SYNCHRO ECAM" button to get back to LDG PERF the ECAM alerts that affect the landing.
This action synchronizes the aircraft status of LDG PERF with the current ECAM alert items listed on the ECAM STATUS MORE page.
If the flight crew had previously selected additional ECAM alerts in LDG PERF (displayed in cyan on the AIRCRAFT STATUS panel) and then uses the SYNCHRO ECAM function, these manually entered alerts are lost.

AUTOMATIC SYNCHRONIZATION WITH THE ECAM

The synchronization with the ECAM is automatic if the fight crew:
- Opens LDG PERF, or
- Changes from an application of the FLT OPS domain to LDG PERF, or
- Changes from the DISPATCH mode to the IN-FLIGHT mode in LDG PERF.

If an ECAM alert that affects the landing performance occurs while the flight crew is using LDG PERF in DISPATCH mode, LDG PERF displays the following popup message:

ECAM alert: popup message in DISPATCH mode



Note: *In the case of a dispatch with a MEL item that results from an ECAM alert affecting the landing performance during the previous flight, the list of the ECAM alert items is still on the STATUS MORE page of the SD. The list of the ECAM alert items of the previous flight is sent to LDG PERF.*

Workaround:

- *If there is no additional ECAM alert during the current flight: Manually deselect the list of the ECAM alert items in LDG PERF*
- *If there are additional ECAM alerts during the current flight: Deselect the list of the ECAM alert items in LDG PERF that are associated with the MEL dispatch.*

Intentionally left blank

RESULTS DATA

Applicable to: ALL

GENERAL

A landing performance calculation computes the following results:

- The landing weights

L2 For more information about the landing weights, *Refer to PER-LND-LRD-DSR Landing Weights* .

L1 - The landing distances

L2 For more information about the landing distances, *Refer to PER-LND-LRD-DSR Landing Distances* .

L1 - The landing limitation codes

L2 For more information about the landing limitation codes, *Refer to PER-LND-LRD-DSR Landing Limitation Codes* .

L1 - The aerodynamic configuration

L2 For more information about the aerodynamic configuration, *Refer to PER-LND-LRD-DSR Aerodynamic Configuration* .

L1 - The go-around gradient

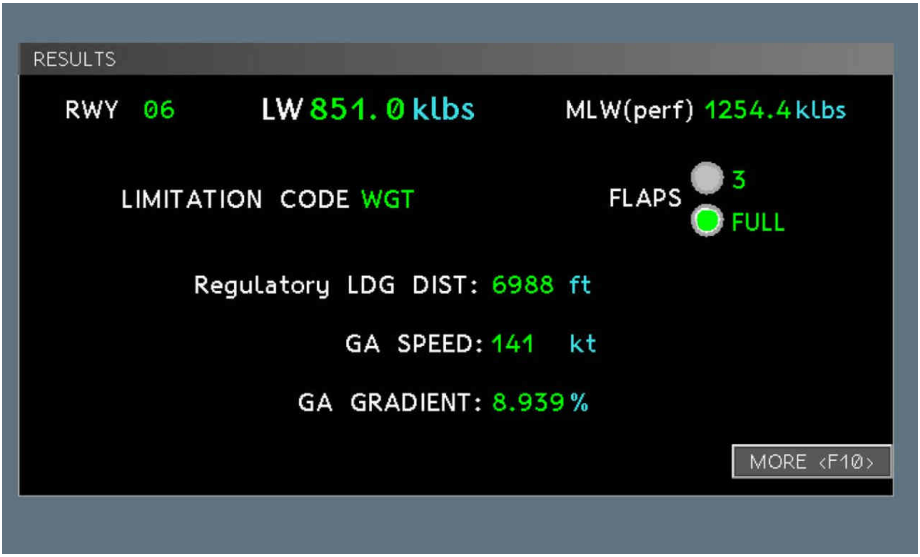
L2 For more information about the go-around gradient, *Refer to PER-LND-LRD-DSR Go-Around Gradient* .

L1 - The go-around speed.

L2 For more information about the go-around speed, *Refer to PER-LND-LRD-DSR Go-Around Speed* .

L1 **LDG PERF**

RESULTS Panel



LANDING WEIGHTS

Applicable to: ALL

GENERAL

The Maximum Landing Weight Limited by the Performance (MLW(PERF)) is the maximum aircraft weight which complies with all the regulatory requirements for landing performance in given environmental conditions.
The MLW(PERF) value may exceed the certified MLW value. The calculation with a LW above the certified MLW (overweight) is possible only in flight.

L2 For an applicable value of MLW , *Refer to FCOM Limitations* .

L1 LDG PERF

The RESULTS panel displays the following two weights:
- LW, the input weight of the calculation
- MLW(perf).

COMMUNICATION FROM LDG PERF TO LOADSHEET

When the flight crew completes a LDG PERF computation and then changes from LDG PERF to LOADSHEET, LDG PERF transfers the calculated MLW(PERF) value to LOADSHEET if the MLW(PERF) value is lower than or equal to the certified MLW value. If the MLW(PERF) value is transferred, LOADSHEET displays this value in yellow in the MLW field of the CONDITIONS panel.

LANDING DISTANCES

Applicable to: ALL

GENERAL

LDA at destination must at least be equal to the RLD for the planned LW and the forecasted conditions.
For more information about landing distances, *Refer to PER-LND-GEN Landing Distance Definitions* .

LDG PERF

Regulatory LDG DIST on the RESULTS panel is the RLD .

L2 When the flight crew runs a LDG PERF computation with the LDG TECHNIQUE Autoland, LDG PERF automatically checks that the RLD for automatic landing is more than or equal to the RLD in manual mode:

- If the RLD for automatic landing is more than or equal to the RLD in manual mode, LDG PERF displays the results for a RLD calculated using the Autoland landing technique
- If the RLD for automatic landing is less than the RLD in manual mode, LDG PERF displays the results for a RLD calculated using the Manual landing technique.

LANDING LIMITATION CODES

Applicable to: ALL

GENERAL

Several regulatory requirements limit landing performance. They are called landing limitations.

LDG PERF

The limitation code identifies the regulatory requirement that limits the MLW(PERF).
If the LW is below the MLW(PERF), the limitation code displays WGT.
The following table describes the meaning of the codes:

WGT	Input Weight
LDA	Landing Distance Available
ACG	Approach Climb Gradient
LCG	Landing Climb Gradient
TIRE	Maximum Tire Speed
BRK	Maximum Brake Energy

Customized codes may differ from the above list.

AERODYNAMIC CONFIGURATION

Applicable to: ALL

GENERAL

For more information about aerodynamic configuration, *Refer to Aerodynamic Configuration (Input)* .

LDG PERF

FLAPS on the RESULTS panel is the configuration selected by the flight crew or the result of the optimization with the AUTO CONF option.

When the flight crew selects AUTO CONF, LDG PERF computes the landing performance for:
- Landing in CONF FULL (go-around in CONF 3)
- Landing in CONF 3 (go-around in CONF 2).

If both a go-around in CONF 3 (landing in CONF FULL) and a go-around in CONF 2 (landing in CONF 3) comply with the go-around gradient constraint, then LDG PERF displays the results for: landing in CONF FULL (go-around in CONF 3).
If a go-around in CONF 3 (landing in CONF FULL) does not comply with the go-around gradient constraint, the flight crew lands in CONF 3 and performs go-around in CONF 2. LDG PERF displays the results for: landing in CONF 3 (go-around in CONF 2).

GO-AROUND GRADIENT

Applicable to: ALL

GENERAL

As per regulation, the aircraft must achieve a minimum climb gradient in the case of a go-around. The go-around gradient is the minimum of the approach climb gradient and the landing climb gradient.

APPROACH CLIMB

The approach climb is based on the following assumptions:

- One engine is inoperative
- The engine thrust rating on the remaining engines is TOGA
- The landing gear is retracted
- The flaps are in approach configuration (CONF 3, 2 and 1+F are certified)
- The go-around speed is higher than VMCL
- The go-around speed is equal to:
  - For CAT I approach type: VLS (1.23 VS1G) of the approach configuration
  - For CAT II approach type: The maximum of:
    - VLS of the approach configuration (landing gear retracted)
    - VLS of the landing configuration (landing gear extended) + 5 kt
    - Minimum Control Airspeed for Landing (VMCL) + 5 kt .

The minimum approach climb gradient is 2.7 % .

LANDING CLIMB

The landing climb is based on the following assumptions:

- All engines are operative
- The thrust is the thrust available 8 s after initiation of thrust control movement from minimum flight idle to TOGA thrust
- The landing gear is extended
- The flaps are in landing configuration (CONF 3 or FULL)
- The go-around speed is higher than VMCL
- The go-around speed is equal to VLS of the landing configuration.

The minimum approach climb gradient is 3.2 % .

L2 The landing climb regulatory requirement is never limiting for landing performance compared to the approach climb regulatory requirement.

L1 **LDG PERF**

GA GRADIENT on the RESULTS panel is the maximum go-around gradient.

L2 For more information about Go-Around Gradient, *Refer to PER-LND-LCD-ACC Go-Around Gradient* .

GO-AROUND SPEED

Applicable to: ALL

For the A380, there is no optimization of the go-around speed.

For the approach climb gradient calculation, the go-around speed is equal to:

- For CAT I approach type: VLS (1.23 VS1G) of the approach configuration
- For CAT II approach type: The maximum of:
  - VLS of the approach configuration (landing gear retracted)
  - VLS of the landing configuration (landing gear extended) + 5 kt
  - Minimum Control Airspeed for Landing (VMCL) + 5 kt.

For the landing climb gradient calculation, the go-around speed is equal to VLS of the landing configuration.

MORE PANEL

Applicable to: ALL

The MORE panel displays the following information:

- The basic results of the LDG PERF computation, plus the Actual LDG DIST and the RWY Length
- The thrust reverser status for the LDG PERF computation:
  - For dry and wet runway conditions, the thrust reverser status is: NO REVERSE THRUST CREDIT
  - For contaminated runways, the thrust reverser status is defined as per Operator policy.
- Additional results data that the Operator can customize.

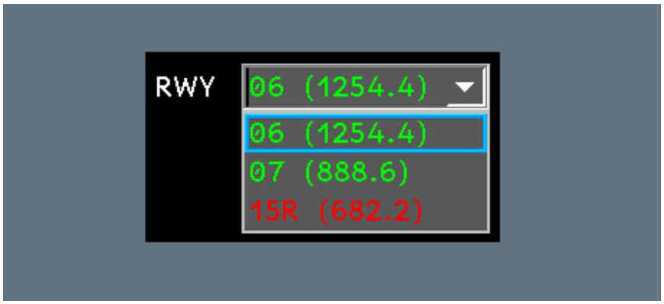
MORE Panel

COMPUTATION RESULTS

Applicable to: ALL

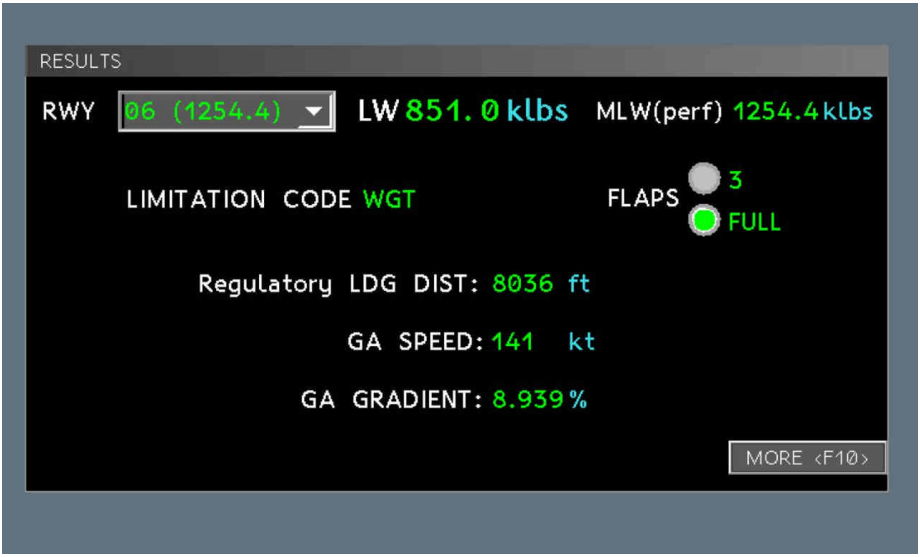
The flight crew uses the RWY drop-down list to access the results for each runway.
For each runway, the MLW(PERF) is displayed between brackets after the Runway ID.

Runway Selection



The list is sorted by weight from the highest to the lowest and is color-coded:
- Green: When the MLW(PERF) is more or equal to the LW
- Red: When the MLW(PERF) is less to the LW .

RESULTS Panel - MULTIPLE RWY COMPUTATION



RESULTS DATA

Applicable to: ALL

GENERAL

A landing performance calculation computes the following results:

- The landing weights

L2 For more information about the landing weights, *Refer to PER-LND-LRF-FSR Landing Weights* .

L1 - The landing distances

L2 For more information about the landing distances, *Refer to PER-LND-LRF-FSR Landing Distances* .

L1 - The stop margin

L2 For more information about the stop margin, *Refer to PER-LND-LRF-FSR Stop Margin* .

L1 - The landing limitation codes

L2 For more information about the landing limitation codes, *Refer to PER-LND-LRF-FSR Landing Limitation Codes* .

L1 - The aerodynamic configuration

L2 For more information about the aerodynamic configuration, *Refer to PER-LND-LRF-FSR Aerodynamic Configuration* .

L1 - The go-around gradient

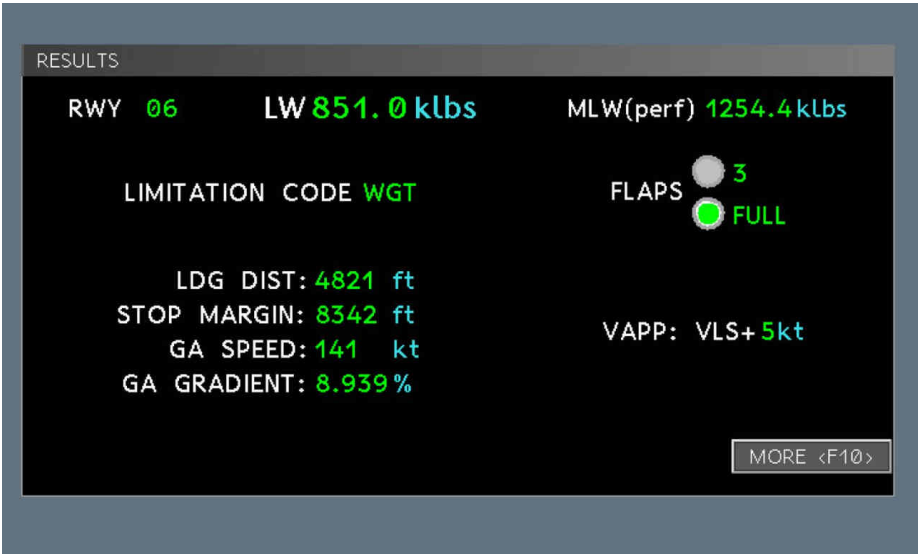
L2 For more information about the go-around gradient, *Refer to PER-LND-LRF-FSR Go-Around Gradient* .

L1 - The go-around speed.

L2 For more information about the go-around speed, *Refer to PER-LND-LRF-FSR Go-Around Speed* .

L1 **LDG PERF**

RESULTS Panel



LANDING WEIGHTS

Applicable to: ALL

GENERAL

The Maximum Landing Weight Limited by the Performance (MLW(PERF)) is the maximum aircraft weight which complies with all the regulatory requirements for landing performance in given environmental conditions.
The MLW(PERF) value may exceed the certified MLW value.

L2 For more information about the overweight landing, *Refer to PER-LND-GEN Overweight Landing Requirements* .
For an applicable value of MLW , *Refer to FCOM Limitations* .

L1 LDG PERF

The RESULTS panel displays the following two weights:
- LW, the input weight of the calculation
- MLW(perf).

In the case of an overweight landing, LDG PERF displays the label OVERWEIGHT LANDING at the top of the RESULTS panel.

COMMUNICATION FROM LDG PERF TO LOADSHEET

When the flight crew completes a LDG PERF computation and then changes from LDG PERF to LOADSHEET, LDG PERF transfers the calculated MLW(PERF) value to LOADSHEET if the MLW(PERF) value is lower than or equal to the certified MLW value. If the MLW(PERF) value is transferred, LOADSHEET displays this value in yellow in the MLW field of the CONDITIONS panel.

LANDING DISTANCES

Applicable to: ALL

GENERAL

LDA at destination must at least be equal to the ALD for the planned LW and the forecasted conditions.
For more information about the landing distances, *Refer to PER-LND-GEN Landing Distance Definitions* .

LDG PERF

LDG DIST on the RESULTS panel is the ALD .

STOP MARGIN

Applicable to: ALL

GENERAL

For in-flight calculation, the stop margin is the difference between the Landing Distance Available (LDA) and the Actual Landing Distance (ALD).
STOP MARGIN = LDA - ALD.

LDG PERF

STOP MARGIN on the RESULTS panel is equal to: RWY LENGTH - LDG DIST.

LANDING LIMITATION CODES

Applicable to: ALL

GENERAL

Several regulatory requirements limit landing performance. They are called landing limitations.

LDG PERF

The limitation code identifies the regulatory requirement that limits the MLW(PERF).
If the LW is below the MLW(PERF), the limitation code displays WGT.
The following table describes the meaning of the codes:

WGT	Input Weight
LDA	Landing Distance Available
ACG	Approach Climb Gradient
LCG	Landing Climb Gradient
TIRE	Maximum Tire Speed
BRK	Maximum Brake Energy

Customized codes may differ from the above list.

AERODYNAMIC CONFIGURATION

Applicable to: ALL

GENERAL

For more information about aerodynamic configuration, *Refer to Aerodynamic Configuration (Input)* .

LDG PERF

FLAPS on the RESULTS panel is the configuration selected by the flight crew or the result of the optimization with the AUTO CONF option.

When the flight crew selects AUTO CONF, LDG PERF computes the landing performance for:
- Landing in CONF FULL (go-around in CONF 3)
- Landing in CONF 3 (go-around in CONF 2).

If both a go-around in CONF 3 (landing in CONF FULL) and a go-around in CONF 2 (landing in CONF 3) comply with the go-around gradient constraint, then LDG PERF displays the results for: landing in CONF FULL (go-around in CONF 3).
If a go-around in CONF 3 (landing in CONF FULL) does not comply with the go-around gradient constraint, the flight crew lands in CONF 3 and performs go-around in CONF 2. LDG PERF displays the results for: landing in CONF 3 (go-around in CONF 2).

OVERWEIGHT LANDING

In the case of an overweight landing, when the flight crew selects AUTO CONF, LDG PERF computes the following scenarios:
1. Landing in CONF FULL, go-around in CONF 3
2. Landing in CONF 3, go-around in CONF 2
3. Landing in CONF 3, go-around in CONF 1+F.

The last scenario (3) is computed only if the first two scenarios failed to give a result. In other words, the last scenario is computed only if a go-around in CONF 2 does not comply with the go-around gradient constraint.
However, as per the FCOM Overweight Landing Procedure: “In all cases, if the landing configuration is different from CONF FULL, use FLAP 1 for go-around”.

L2 For more information about the overweight landing procedure:
- *Refer to FCOM - Overweight Landing Procedure*
- *Refer to FCTM/ FCTM - Overweight Landing Procedure* .

L1 Therefore, in the case of an overweight landing, the flight crew may select AUTO CONF to determine the adequate aerodynamic configuration to use for the overweight landing. If the result of the LDG PERF computation is: landing in CONF 3 and go-around in CONF 2, the flight

crew manually selects CONF 3 for LDG CONF and CONF 1+F for GA CONF. Then the flight crew restarts the computation.

GO-AROUND GRADIENT

Applicable to: ALL

GENERAL

As per regulation, the aircraft must achieve a minimum climb gradient in the case of a go-around. The go-around gradient is the minimum of the approach climb gradient and the landing climb gradient.

APPROACH CLIMB

The approach climb is based on the following assumptions:

- One engine is inoperative
- The engine thrust rating on the remaining engines is TOGA
- The landing gear is retracted
- The flaps are in approach configuration (CONF 3, 2 and 1+F are certified)
- The go-around speed is higher than VMCL
- The go-around speed is equal to:
  - For CAT I approach type: VLS (1.23 VS1G) of the approach configuration
  - For CAT II approach type: The maximum of:
    - VLS of the approach configuration (landing gear retracted)
    - VLS of the landing configuration (landing gear extended) + 5 kt
    - Minimum Control Airspeed for Landing (VMCL) + 5 kt .

The minimum approach climb gradient is 2.7 % .

LANDING CLIMB

The landing climb is based on the following assumptions:

- All engines are operative
- The thrust is the thrust available 8 s after initiation of thrust control movement from minimum flight idle to TOGA thrust
- The landing gear is extended
- The flaps are in landing configuration (CONF 3 or FULL)
- The go-around speed is higher than VMCL
- The go-around speed is equal to VLS of the landing configuration.

The minimum approach climb gradient is 3.2 % .

L2 The landing climb regulatory requirement is never limiting for landing performance compared to the approach climb regulatory requirement.

L1 **LDG PERF**

GA GRADIENT on the RESULTS panel is the maximum go-around gradient.

L2 For more information about Go-Around Gradient, *Refer to PER-LND-LCF-ACC Go-Around Gradient* .

GO-AROUND SPEED

Applicable to: ALL

For the A380, there is no optimization of the go-around speed.

For the approach climb gradient calculation, the go-around speed is equal to:

- For CAT I approach type: VLS (1.23 VS1G) of the approach configuration
- For CAT II approach type: The maximum of:
  - VLS of the approach configuration (landing gear retracted)
  - VLS of the landing configuration (landing gear extended) + 5 kt
  - Minimum Control Airspeed for Landing (VMCL) + 5 kt.

For the landing climb gradient calculation, the go-around speed is equal to VLS of the landing configuration.

LANDING SPEED

Applicable to: ALL

GENERAL

The Approach Speed (VAPP) is the speed of the aircraft 50 ft above the runway.

VAPP is the sum of:

- VLS

L2 VLS is the Lowest Selectable Speed
VLS is equal to 1.23 VS1G

L1 - The wind speed increment

L2 The wind correction is equal to 1/3 of the headwind. The wind correction is limited to 15 kt.
When A/THR is selected, a minimum wind correction of 5 kt is required.

L1 - The CDL speed increment
- The ECAM alert speed increment
- An extra value selected at the flight crew discretion.

LDG PERF

NO ECAM ALERT ITEM SELECTED

VAPP on the RESULTS panel is the sum of:

- VLS
- VLS+, the speed increment entered by the flight crew on the CONDITIONS panel
- ΔVCDL, the speed increment in VAPP due to the selected CDL item(s), if the flight crew has selected a CDL item that affects VAPP.

ECAM ALERT ITEM SELECTED

VAPP on the RESULTS panel is equal to the sum of:

- Vref, which is equal to VLS
- ΔVref, which is detailed on the MORE panel and is equal to the sum of:
  - ΔVfailure, the ECAM alert speed increment, when an ECAM alert item that affects the approach speed is selected
  - ΔVwind, the wind speed increment

L2 The wind correction is equal to 1/3 of the headwind. The wind correction is limited to 15 kt.

L1
  - ΔVpilot, the speed increment entered by the flight crew on the CONDITIONS panel
  - ΔVcdl, the CDL speed increment, if the flight crew has selected a CDL item that affects the approach speed.

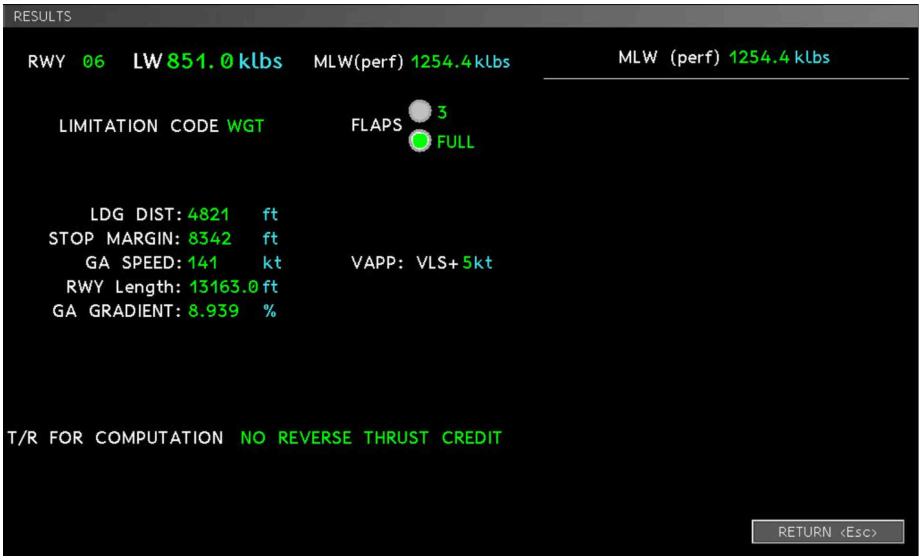
MORE PANEL

Applicable to: ALL

The MORE panel displays the following information:

- The basic results of the LDG PERF computation, plus the RWY Length
- The thrust reverser status for the LDG PERF computation:
  - For dry and wet runway conditions, the thrust reverser status is: NO REVERSE THRUST CREDIT
  - For contaminated runways, the thrust reverser status is defined as per Operator policy.
- Additional results data that the Operator can customize.

MORE Panel

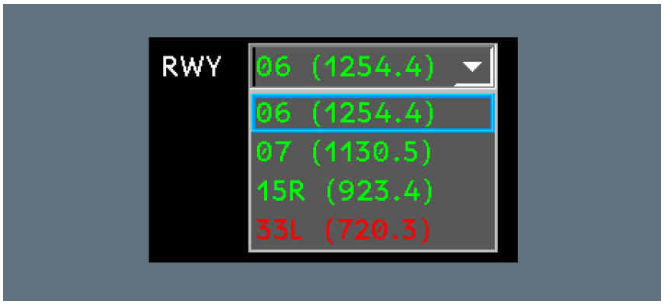


COMPUTATION RESULTS

Applicable to: ALL

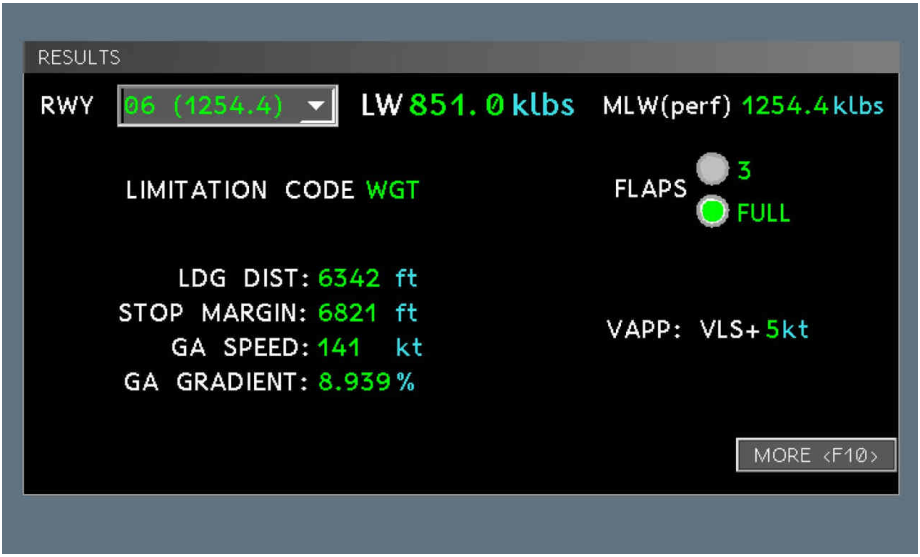
The flight crew uses the RWY drop-down list to access the results for each runway.
For each runway, the MLW(PERF) is displayed between brackets after the Runway ID.

Runway Selection



The list is sorted by weight from the highest to the lowest and is color-coded:
- Green: When the MLW(PERF) is more or equal to the LW
- Red: When the MLW(PERF) is less to the LW .

RESULTS Panel - MULTIPLE RWY COMPUTATION



GENERAL

Applicable to: ALL

LANDING PERFORMANCE ECAM INDICATIONS

After an aircraft system failure that occurs in flight and that affects the landing performance, the flight crew must follow the associated ECAM procedure.
The ECAM displays landing performance indications in the applicable procedure.

L2 For more information about the landing performance ECAM indications, *Refer to DSC-31-40-10 Landing Performance Indications* .

L1 In the case of a landing performance ECAM indication that results in a LDG PERF computation, the flight crew selects the applicable ECAM alert items in the ACFT STATUS panel of LDG PERF - IN-FLIGHT.
The applicable ECAM alert items are listed in the ECAM STATUS MORE page.

LDG PERF COMPUTATION WITH ECAM ALERT

LANDING DISTANCE IMPACT

The runway length for landing is the ALD in CONF FULL without failure multiplied by the landing distance coefficient associated with the applicable ECAM alert item.

On the RESULTS panel of LDG PERF:
- LDG DIST without ECAM is the ALD in CONF FULL without failure
- Failure coefficient is the landing distance coefficient associated with the applicable ECAM alert item
- LDG DIST is equal to LDG DIST without ECAM multiplied by Failure coefficient

VAPP IMPACT

The applicable ECAM alert item may affect the VAPP because of a speed increment due to the system failure (ΔVfailure).
In the case of a ΔVfailure different from 0, the flight crew enters into the FMS - PERF - APPR page the VAPP value computed by LDG PERF - IN-FLIGHT.

L2 For more information about the VAPP value computed by the FMS , *Refer to DSC-22-FMS-20-30-22FMS502BC PERF page - VAPP* .

Intentionally left blank

CONDITIONS

Applicable to: ALL

The selection of an ECAM alert item modifies the CONDITIONS panel.

CONDITIONS Panel

LDG CONF

The LDG CONF field disappears.

L2 The LDG CONF is a result of a computation with an ECAM alert, and not an input.

L1 LDG CG

The LDG CG field appears.
In this field, the flight crew enters the estimated CG at landing.
The CG field enables the flight crew to reduce conservatism on the approach speed in such a degraded situation. The Approach Speed (VAPP) computation takes into account the value that the flight crew enters in the CG field, but the landing distance computation considers that the CG is at the most forward limit.

$\Delta V_{FAILURE} = 0$

For ECAM alerts that do not affect the VAPP , LDG CG enables to calculate the landing distance using the best VLS assessment (as VLS depends on CG).

$\Delta V_{FAILURE} \neq 0$

For ECAM alerts that affect the VAPP , LDG CG enables:

- To calculate the landing distance using the best VLS assessment (as VLS depends on CG)
- To determine the most relevant VAPP at landing.
  LDG PERF is the reference tool for the VAPP determination in the case of ECAM alert(s) that affect the VAPP .

VPILOT

The VPilot field appears instead of VLS+.
VPilot is the speed increment entered by the flight crew in order to increase the approach speed.
To determine VPilot, *Refer to PER-LND-LFF-CMT VPilot Determination for VAPP Calculation* .

LDG TECHNIQUE

The following error message appears if the flight crew selects the LDG TECHNIQUE Autoland: "Computation using autoland with ECAM Alert is not possible".
The selection of an ECAM alert item plus the LDG TECHNIQUE Autoland is not possible even if the associated ECAM alert does not inhibit the use of the Autoland system.
However, for these failure cases, the distance computed for Manual Landing is consistent with the average landing distance achieved with Autoland.
Therefore, the flight crew can set the LDG TECHNIQUE field to Manual.

BRK MODE

The following error message appears if the flight crew selects an autobrake mode: "Computation using autobrake mode with ECAM Alert is not possible".
The failure coefficients are computed without autobrake (i.e. with maximum pedal braking).
Therefore, the flight crew must set the BRAKE MODE field to Manual.

L2 Autobrake may be used operationally at the flight crew discretion when sufficient performance margins are available.

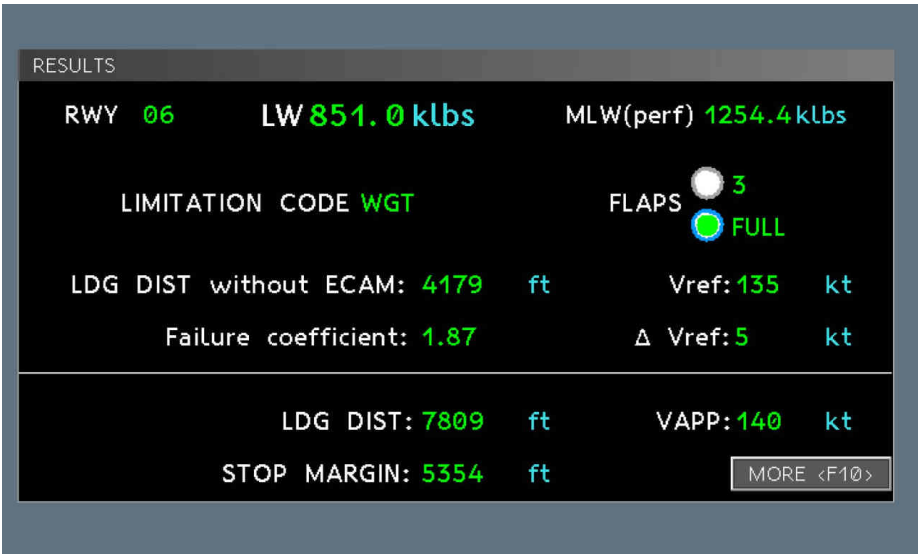
BASIC RESULTS

Applicable to: ALL

The selection of an ECAM alert item modifies the RESULTS panel.
For ECAM alert items that do not require a specific flaps lever position for landing, the landing can be performed in both CONF FULL and CONF 3. The default LDG PERF computation considers CONF FULL. The flight crew can use the buttons FLAPS 3 and FLAPS FULL to access the appropriate landing performance and approach speeds on the RESULTS panel.

FLAPS FULL

RESULTS Panel: FLAPS FULL



LDG DIST WITHOUT ECAM

LDG DIST without ECAM is the distance necessary for the aircraft to land, considering that the aircraft has no failure.

FAILURE COEFFICIENT

Failure coefficient is the coefficient that LDG PERF applies to LDG DIST without ECAM to compute LDG DIST.

VREF

Vref is the VLS of the aircraft calculated with FULL flaps setting.

ΔVREF

ΔVref is the sum of:

- ΔVfailure, the speed increment due to the system failure
  L2 ΔVfailure is calculated by LDG PERF.
- L1 ΔVwind, the speed increment due to the wind correction
  L2 ΔVwind is calculated by LDG PERF.
  For more information about the ΔVwind calculation, *Refer to PER-LND-LFF-CMT VPilot Determination for VAPP Calculation* .
- L1 ΔVPilot, equal to the VPilot entered by the flight crew on the CONDITIONS panel
  L2 For more information about how to determine VPilot, *Refer to PER-LND-LFF-CMT VPilot Determination for VAPP Calculation* .
- L1 ΔVcdl, the speed increment due to the selected CDL item(s), only if the following CDL items are selected:
  - POWER PLANT ATA71-15 NACELLE STRAKES, and/or
  - FLIGHT CONTROLS ATA27-22 FLAP END SEAL.

LDG DIST

LDG DIST is the distance necessary for the aircraft to land. This distance takes into account the aircraft system failures selected. LDG DIST is equal to LDG DIST without ECAM multiplied by Failure coefficient.

STOP MARGIN

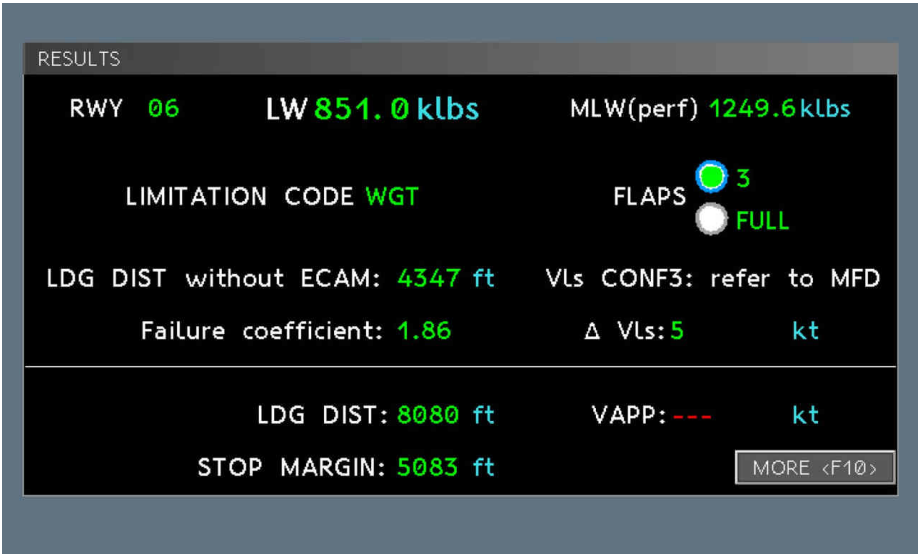
STOP MARGIN is the difference between the LDA and LDG DIST.

VAPP

VAPP is the sum of Vref and ΔVref. To determine VAPP , *Refer to PER-LND-LFF-CMT VPilot Determination for VAPP Calculation* .

FLAPS 3

BASIC Results: FLAPS 3



The layout of the RESULTS panel is slightly modified.
Vls CONF 3 replaces VREF and ΔVls replaces ΔVref.

VLS CONF 3

LDG PERF does not calculate Vls CONF 3.
The reference remains the VLS value displayed on the FMS - PERF - APPR page.

ΔVLS

ΔVls is the sum of:

- ΔVfailure, the speed increment due to the system failure

L2 ΔVfailure is calculated by LDG PERF.

- L1 L2 ΔVwind, the speed increment due to the wind correction

ΔVwind is calculated by LDG PERF.
For more information about ΔVwind calculation, *Refer to PER-LND-LFF-CMT VPilot Determination for VAPP Calculation* .

- L1 L2 ΔVPilot, which is equal to the VPilot entered by the flight crew on the CONDITIONS panel

To determine VPilot, *Refer to PER-LND-LFF-CMT VPilot Determination for VAPP Calculation* .

L1 - ΔVcdl, which is different from zero only if one or both of the following CDL items are selected:

- POWER PLANT ATA71-15 NACELLE STRAKES
- FLIGHT CONTROLS ATA27-22 FLAP END SEAL.

VAPP

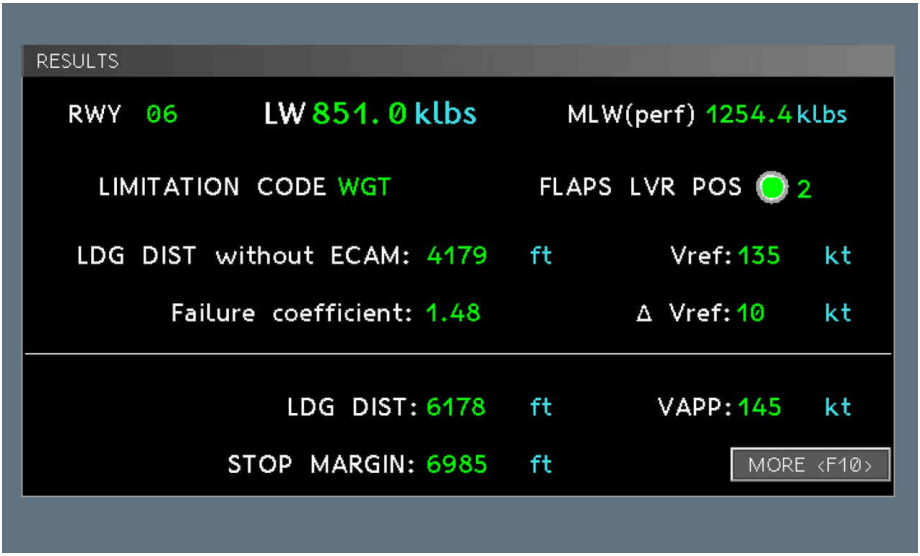
VAPP is the sum of Vls and ΔVls.
As LDG PERF does not calculate Vls CONF 3, LDG PERF does not calculate VAPP.

BASIC RESULTS: SPECIFIC FLAPS LEVER POSITION

Applicable to: ALL

Some ECAM alerts require a specific flaps lever position for the landing.
FLAPS LVR POS on the RESULTS panel is the configuration required by the ECAM alert for the landing.

BASIC Results: Specific Flaps Lever Position

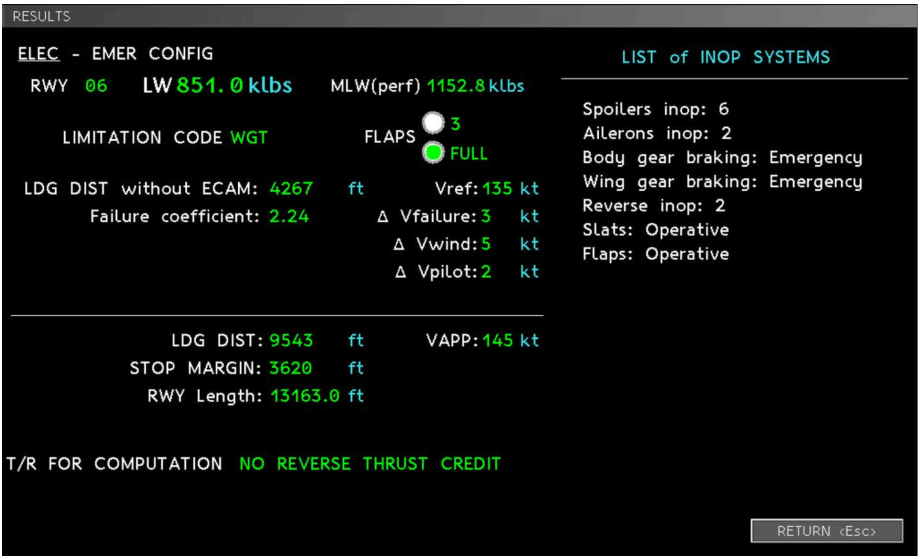


MORE PANEL

Applicable to: ALL

The selection of an ECAM alert item modifies the MORE panel.

MORE Panel



Note: If the flight crew select FLAPS 3, the layout is slightly modified as Vls CONF 3 replaces Vref.

ΔVFAILURE

ΔVfailure is the speed increment due to the failure.
ΔVfailure is calculated by LDG PERF.

ΔVWIND

ΔVwind is the speed increment due to the wind correction.
ΔVwind is calculated by LDG PERF.

L2 For more information about the ΔVwind calculation, *Refer to PER-LND-LFF-CMT VPilot Determination for VAPP Calculation* .

L1 ΔVPILOT

ΔVPilot is equal to the VPilot entered by the flight crew on the CONDITIONS panel.

L2 For more information about how to determine VPilot, *Refer to PER-LND-LFF-CMT VPilot Determination for VAPP Calculation* .

L1 **ΔVCDL**

ΔVcdl is displayed only if the following CDL items are selected:
- POWER PLANT ATA71-15 NACELLE STRAKES, and/or
- FLIGHT CONTROLS ATA27-22 FLAP END SEAL.

ΔVcdl is the speed increment due to the selected CDL item(s).

LIST OF INOP SYSTEMS

The LIST of INOP SYSTEMS panel displays the list of the systems that are considered to be inoperative due to the selected ECAM alert(s).

CALCULATION SEQUENCE

Applicable to: ALL

During a flight following failure, the flight crew must verify that the LDA of the expected runway is longer than the actual landing distance with failure at the expected landing weight in forecasted conditions.

If the flight crew has selected one or several ECAM Alerts items, the following calculation sequence is recommended:

1. The computation is first made at current conditions with VPilot = 0
2. In the RESULTS MORE panel, the flight crew checks the value of the increment in VAPP : ΔVfailure and ΔVwind
3. If ΔVfailure > 5 kt OR ΔVwind ≥ 5 kt OR the landing is planned with A/THR disengaged: Minimum VPilot = 0.
   The first calculation is sufficient
4. If ΔVfailure ≤ 5 kt AND ΔVwind < 5 kt AND the landing is planned with A/THR engaged: Minimum VPilot = " 5 kt - ΔVwind".
   The flight crew performs an additional landing calculation with at least the value of Minimum VPilot.

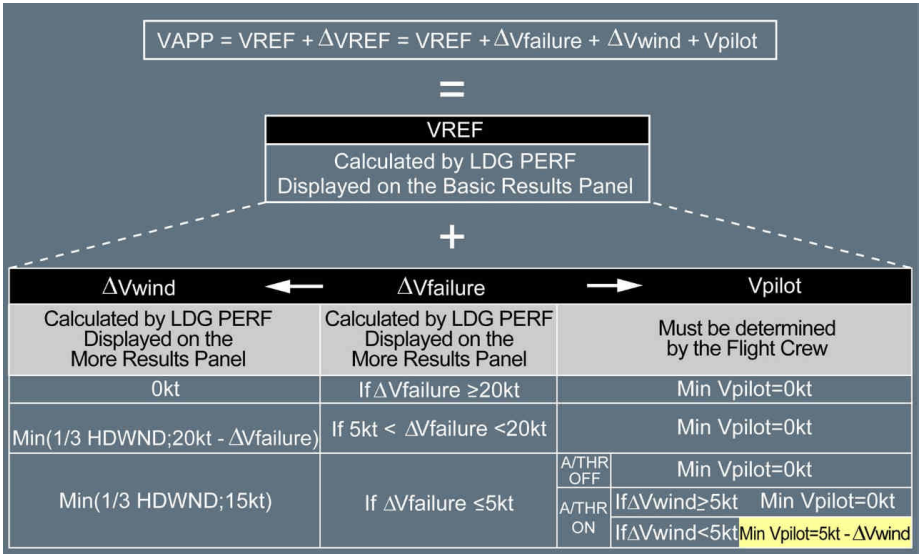
For more information on VPilot determination, *Refer to PER-LND-LFF-CMT VPilot Determination for VAPP Calculation* .

Note: *If ΔVcdl is displayed and different from 0, add ΔVcdl to ΔVfailure and follow the same calculation sequence.*

VPILOT DETERMINATION FOR VAPP CALCULATION

Applicable to: ALL

VPilot Determination for VAPP Calculation



Note: *If ΔVcdl is displayed and different from 0, add ΔVcdl to ΔVfailure and follow the same calculation sequence.*

DEFINITIONS

Applicable to: ALL

Landing performance is impacted by runway contamination.

CONTAMINANTS

Contaminants can be classified into Fluid and Hard Contaminants:

FLUID CONTAMINANTS

WATER	Wet	Depth of water less or equal to 0.12 in.
	Standing Water	Due to heavy rainfall, and/or insufficient runway drainage. Deeper than 0.12 in.
SLUSH	Water saturated with snow that spatters when stepping firmly on it. Slush occurs at an approximate temperature of 5 °C, and an approximate density of 0.85 kg/l (7.1 lb/US Gal).	
WET SNOW	If compacted by hand, the snow will stick together, and usually forms a snowball. Its density is approximately 0.4 kg/l (3.35 lb/US Gal).	
DRY SNOW	Can be blown if loose, or if compacted by hand, will fall apart again upon release. Its density is approximately 0.2 kg/l (1.7 lb/US Gal).	

HARD CONTAMINANTS

COMPACTED SNOW	Snow that has been compressed (the usual friction coefficient is 0.2).
ICE	In icy conditions, the friction coefficient is 0.05 or below.

STATE OF RUNWAY

The contaminant characteristics (type, depth, appearance) determine the state of the runway.

DRY	A runway is dry when its surface is not: - Damp - Wet - Contaminated.
DAMP	A runway is damp: - When its surface is not dry - But when the water on it does not give it a shiny appearance.
WET	A runway is considered as wet: - When its surface has a shiny appearance - Due to a thin layer of Fluid Contaminant - With no substantial risk of hydroplaning. For Water, this layer may not exceed 0.12 in depth.
CONTAMINATED	A runway is contaminated when more than 25 % of its surface is covered with: - A layer of Fluid Contaminant that is not considered as thin

Continued on the following page

Continued from the previous page

	- A Hard Contaminant.

EFFECT ON PERFORMANCE

Applicable to: ALL

Contaminants are classified by their effect on aircraft performance.

FLUID CONTAMINANTS

Fluid Contaminants reduce friction forces, and cause:
- Precipitation drag
- Hydroplaning.

PRECIPITATION DRAG

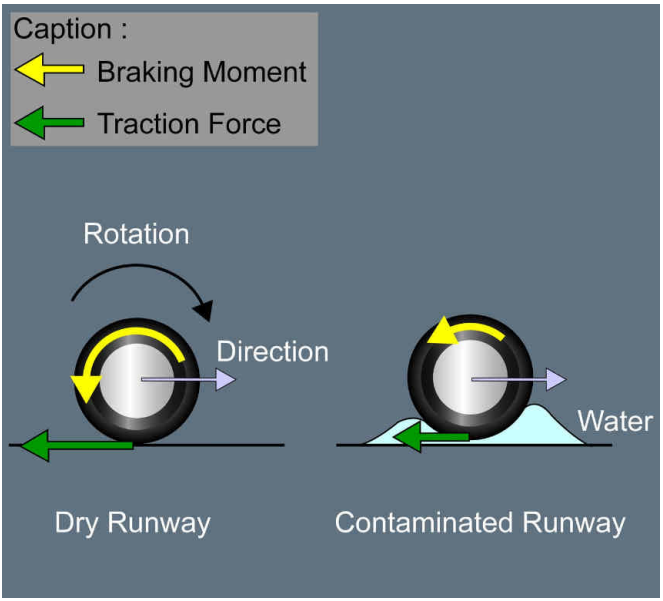
L2 Precipitation drag includes:
- Displacement drag, that is produced by the displacement of the contaminant fluid from the path of the tire
- Spray impingement drag, that is produced by the spray thrown up by the wheels (mainly those of the Nose Landing Gear (NLG)) onto the fuselage.

L1 Precipitation drag improves the deceleration rate and has a beneficial effect on landing performance.

HYDROPLANING

L2 If there is water on the runway, a water film is created between the tire and the runway, that causes a reduction in the dry contact surface area between the tire and the runway.
This phenomenon becomes more critical at high speeds, when the rolling tire cannot evacuate the water fast enough.
Hydroplaning is a situation where the tires of the aircraft are, to a large extent, separated from the runway surface while floating on a thin film of fluid.
During hydroplaning, tire traction decreases to almost negligible values, thus rendering wheel braking and steering virtually ineffective.

Hydroplaning Phenomenon



Hydroplaning speed depends on tire pressure, and on the specific gravity of the contaminant (i.e. how dense the contaminant is).

L1 The hydroplaning speed is a threshold above which friction forces are severely reduced. Performance calculations on contaminated runways take into account the penalizing effect of hydroplaning.

HARD CONTAMINANTS

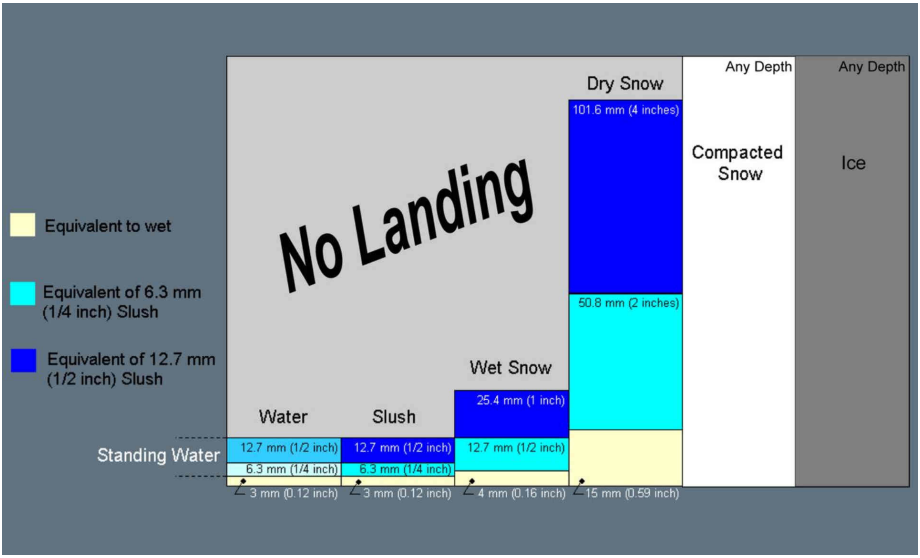
Hard Contaminants only reduce friction forces.

L2 The tires roll on top of a flat layer of Hard Contaminant. Therefore, only the friction coefficient (effective μ) is reduced, the depth of contaminant has no influence on landing performance.

EQUIVALENCES FOR PERFORMANCE

Applicable to: ALL

Runway Conditions



Landing performance is established only for some well-identified certified runway conditions. Within limits, it is possible to take into account other runway condition that may be encountered in operation, by using one of the identified states that has an equivalent impact on performance.

WET RUNWAY

In terms of performance, a Fluid Contamination is equivalent to wet, up to a maximum depth of:

- 3 mm (0.12 in) Water,
- 3 mm (0.12 in) Slush,
- 4 mm (0.16 in) Wet Snow,
- 15 mm (0.59 in) Dry Snow.

For more information on wet runway, *Refer to PER-LND-CTA Definitions* .

CONTAMINATED RUNWAY

In terms of performance, an equivalence between Dry and Wet Snow and the certified contaminated runway conditions is defined.

EQUIVALENTS OF 6.3 MM (1/4 IN) SLUSH

- 12.7 mm (1/2 in) Wet Snow is equivalent to 6.3 mm (1/4 in) Slush,
- 50.8 mm (2 in) Dry Snow is equivalent to 6.3 mm (1/4 in) Slush.

EQUIVALENTS OF 12.7 MM (1/2 IN) SLUSH

- 25.4 mm (1 in) Wet Snow is equivalent to 12.7 mm (1/2 in) Slush,
- 101.6 mm (4 in) Dry Snow is equivalent to 12.7 mm (1/2 in) Slush.

For more information on contaminated runway, *Refer to PER-LND-CTA Definitions* .

EFFECTIVE AND REPORTED FRICTION COEFFICIENTS

Applicable to: ALL

Airport authorities publish runway contamination data in a document called “SNOWTAM”, that includes:

- The type of contaminant
- The average depth for each third of total runway length
- The reported friction coefficient, or braking action.

The reported Friction coefficient (μ) is measured by friction-measurement vehicles, usually at comparatively low speed. However, the friction forces that are applicable to an aircraft (interaction tire/runway) depend on the weight on wheels, tire pressure, anti-skid system efficiency and ground speed.
No universal correlation has been identified between the figures obtained from these measurement vehicles (reported μ), and the actual braking performance of an aircraft (effective μ).
In the case of runway contamination, the performance data is calculated for several well-identified types and depths of contaminant, and not as a function of the aircraft’s effective μ, except if the operator experience has permitted to establish such a correlation.

COMPUTATION ASSUMPTIONS

Applicable to: ALL

In the case of runway contamination, landing performance calculations are based on the following assumptions:

- The contaminant covers the entire length of the runway in a layer that has a uniform depth and density
- The friction coefficient is defined by the applicable regulation.

In addition, for fluid contaminated runways only:

- Drag increases, due to rolling resistance of the wheels
- Drag increases, due to the spray from the Nose Landing Gear (NLG) on the airframe and on the main gears
- Reverse thrust credit may be used for the deceleration phase.

CROSSWIND

Applicable to: ALL

It is not recommended to land with a crosswind component higher than the one that appears in the table below:

Reported Braking Action	Reported Runway Friction Coefficient	Maximum Crosswind (kt)	Equivalent Runway Condition(2)
Good	≥ 0.4	35 kt (1)	1
Good/Medium	0.39 to 0.36	27 kt	1
Medium	0.35 to 0.3	20 kt	2/3
Medium/Poor	0.29 to 0.26	20 kt	2/3
Poor	≤ 0.25	15 kt	3/4
Unreliable		5 kt	4/5

(1) This is the maximum crosswind for dry and wet runway gust included.

(2) Equivalent runway condition (only valid in determining the maximum crosswind):

1. *Dry, damp or Wet runway covered with Water.*
2. *Runway covered with Slush.*
3. *Runway covered with Dry Snow.*
4. *Runway covered with Standing Water, with risk of hydroplaning or Wet Snow.*
5. *Icy runway or high risk of hydroplaning.*

It is not recommended to land with a crosswind component higher than the one that appears in the table below:

Runway Condition(2)	Maximum Crosswind (kt)
1	35 kt (1)
1	27 kt
2/3	20 kt
2/3	20 kt
3/4	15 kt
4/5	5 kt

(1) This is the maximum crosswind for dry and wet runway gust included.

(2) Runway condition (only valid in determining the maximum crosswind):

1. *Dry, damp or Wet runway covered with Water.*
2. *Runway covered with Slush.*
3. *Runway covered with Dry Snow.*
4. *Runway covered with Standing Water, with risk of hydroplaning or Wet Snow.*
5. *Icy runway or high risk of hydroplaning.*

It is not recommended to land with a crosswind component higher than the one that appears in the table below:

Reported Braking Action	Reported Runway Friction Coefficient	Maximum Crosswind (kt)
Good	≥ 0.4	35 kt (1)
Good/Medium	0.39 to 0.36	27 kt
Medium	0.35 to 0.3	20 kt
Medium/Poor	0.29 to 0.26	20 kt
Poor	≤ 0.25	15 kt
Unreliable		5 kt

(1) This is the maximum crosswind for dry and wet runway gust included.

INTRODUCTION

Applicable to: ALL

DEFINITION

An **Operations Engineering Bulletin (OEB)** is issued to rapidly inform operators of any deviations from initial design objectives that have a significant operational impact. An OEB provides the operators with technical information and temporary operational procedures that address these deviations.

TYPE OF OEB

OEB s can either be red or white, depending on their level of priority.

Red OEB s : Are issued to indicate that non-compliance with the recommended procedures may have a significant impact on the safe operation of the aircraft .

White OEB s : Are issued to indicate that non-compliance with the recommended procedures may have a significant impact on aircraft operation.

Airbus strongly recommends that all Operators rapidly apply the OEB corrective actions as soon as they become available, particularly for red OEB s.

The information in the OEB is recommended by Airbus, but may not be approved by Airworthiness Authorities. However, the procedures of the red OEB s are also issued via Temporary Revisions (TRs) of the Airplane Flight Manual (AFM). If the procedures contained in the red OEB differ from the procedures in the AFM TR, the approved AFM TR remains the reference.

OEB CONTENT AND MANAGEMENT

An OEB :

- Is a part of the Flight Crew Operating Manual (FCOM)
- Is temporary and usually focuses on one operational subject only
- Remains applicable until the appropriate corrective actions are completed
- Is filed in numerical order.

The content of each OEB includes:

- The reason for issue
- Technical explanations of the deviation from the initial design objectives
- The operational impact if the flight crew does not apply the OEB procedure
- The conditions for applying the OEB procedures:
  - Cockpit effect
  - Flight phases
  - Specific event.

- The OEB operational procedure(s) to be applied
- The corrective actions that cancel the OEB , if available when the OEB is issued.

If necessary, there are links to the FCOM sections for which the OEB is applicable, and these sections are usually in the format of Temporary Documentary Unit (TDU).

OEB AND ECAM ABNORMAL & EMERGENCY PROCEDURES

OEB s do not impact the ECAM abnormal/emergency procedures.
The Airbus Temporary Quick Change (ATQC) database is used to urgently make any required updates or changes to an ECAM abnormal and emergency procedures. For more information on the ATQC database, *Refer to DSC-31-40-10-BBB ECAM ARchitecture - FWS* .

REVIEW OF THE OEB

In accordance with the Standard Operating Procedures, and before each flight, the flight crew must review all OEB s that are applicable to their aircraft. (*Refer to PRO-NOR-SOP-40-D OIS Preparation_OPERATIONS ENGINEERING BULLETINS (OEB)*) . If the OEB conditions are applicable, the flight crew must apply the operational procedure(s) that is in the OEB .

DISTRIBUTION

OEB s are distributed to all affected Operators. The Operator shall provide flight crews with the content of the OEB without delay.

FCU - ERRONEOUS BAROMETRIC REFERENCE AFTER FCU RESET - APPROVAL

Applicable to: ALL

APPROVAL REFERENCE
APPROVED BY: Head of Flight Operations Support and Services
Approval date: 06 JUN 11
Approval reference: 2011-06-06
Approved by: HO Flight Operations Support and Services

Reason for issue:

This OEB is issued to:

- Inform Operators about the possibility of erroneous barometric reference, following Flight Control Unit (FCU) switched OFF then ON
- Provide operational recommendations in the case the Flight Crew resets the FCU.

Applicable to: All A380 aircraft

Cancelled by: The next PRIM P10 standard

M	Localization	T	DU Title	DU identification	DU date

No bulletin found

Applicable to: ALL

EVENT DESCRIPTION

In the frame of tests on the Flight Control Unit (FCU), Airbus identified the following misbehavior: If the FCU is switched OFF then ON, the barometric reference can erroneously initialize, at FCU power-up, to the default mode and value QNH 1013.

This erroneous barometric reference can appear on:
- One EFIS CP only, or
- Both EFIS CPs simultaneously.

Note: This misbehavior does not affect the barometric reference displayed on the EFIS CP page of the MFD FCU backup. The selection/deselection of the EFIS CP backup page ensures a correct continuity of the barometric reference.

EXPLANATION

The PRIM computers transmit to the FCU the baro-setting data coming from the Air Data Reference (ADR). At FCU power-up, the FCU synchronizes on these PRIM data to initialize. However, due to asynchronous data emission, the FCU can wait for baro-setting data from the PRIM. In this case, a default mode and value are set.
As a result, the barometric reference displayed on the EFIS CP can reset to QNH 1013.

Applicable to: ALL

PROCEDURE

- **In the case of Flight Control Unit (FCU) reset via the FCU brightness knob:**
  Check the barometric reference on both EFIS CPs, and set the appropriate mode and value, if erroneously displayed.
